PROTOCOL SIGNATURE PAGE

Version 1.3 – April 15, 2013

I have read this protocol and agree to adhere to the requirements. I will provide copies of this protocol and all relevant documentation (e.g. Manual of Procedures) to the study personnel that are under my supervision in relation to the D2d study. I will discuss this material with them and ensure that they are fully informed regarding the study procedures and the conduct of the study according to 21 Code of Federal Regulations parts 50, 54, 56 and 312, to Good Clinical Practices as described in International Conference on Harmonization guideline E6, and by Institutional Review Boards.

1. PROTOCOL SYNOPSIS

<i>Title</i>	Vitamin D and type 2 diabetes study (D2d study).
<i>Funding</i>	National Institute of Diabetes and Digestive and Kidney diseases (NIDDK) National Institutes of Health (NIH).
<i>Study Objective</i>	To assess whether, in participants with pre-diabetes, oral daily vitamin D ₃ supplementation reduces the rate of progression from pre-diabetes to clinical diabetes.
<i>Study Design</i>	Multicenter, randomized (1:1), double-masked, placebo-controlled, parallel-group, primary prevention clinical trial with 2 arms (oral daily vitamin D vs. placebo) in participants at high risk for diabetes (with pre-diabetes) who will be followed for an average of 3 years after randomization for incident diabetes.
<i>Intervention</i> <i>Active</i> <i>Placebo</i> <i>Other</i>	-Cholecalciferol (D ₃) 4,000 IU, one soft-gel pill daily -One soft-gel pill daily -At baseline, all participants will receive information on the current lifestyle recommendations for prevention of type 2 diabetes. Twice a year during follow-up, participants will be invited to join a support and education program, set up as a group meeting, to discuss issues on nutrition and physical activity relevant to type 2 diabetes.
<i>Study Population</i>	The study will target persons at increased risk for type 2 diabetes.
Inclusion Criteria	
1. Pre-diabetes (“at increased risk for diabetes”) defined by meeting 2-out-of-3 of the following glycemic criteria, established by the American Diabetes Association (ADA) in the 2010 clinical practice guidelines, at the baseline visit: a. Fasting plasma glucose (FPG) 100-125 mg/dL, inclusive b. 2-hour plasma glucose (2hPG) 140-199 mg/dL, inclusive c. Hemoglobin A1c (HbA1c) 5.7-6.4%, inclusive 2. Age ≥ 30 years. 3. Body Mass Index ≥ 25 (23 kg/m² for Asians) and ≤ 40 kg/m² 4. Provision of signed and dated written informed consent prior to any study procedures.	
Major Exclusion Criteria	
1. Diabetes based on <i>either</i> of the following criteria: a. History (past 1 year) of hypoglycemic pharmacotherapy (oral or injectable medication approved by the FDA for type 2 diabetes) used for any condition (e.g. pre-diabetes, diabetes, polycystic ovarian syndrome). b. Meeting glycemic criteria for diabetes, as defined by the ADA guidelines (FPG ≥ 126 mg/dL, 2hPG ≥ 200 mg/dL or HbA1c ≥ 6.5%). 2. History (past 3 years) of hyperparathyroidism, nephrolithiasis or hypercalcemia. 3. Any medical condition (past 3 years) that in the opinion of the site	

investigator may increase risk for nephrolithiasis or hypercalcemia during the trial (e.g. sarcoidosis).

4. Visit to tanning booth within 12 weeks of the baseline visit and unwilling to stop visiting tanning booths for the duration of the study

Medications and Supplements

5. Use of supplements containing vitamin D at total doses higher than 1000 IU/day within 12 weeks of the baseline visit and unwillingness to limit vitamin D supplementation dosage to no higher than 1000 IU/day for the duration of the study.
6. Use of supplements containing calcium at total doses higher than 600 mg/day within 1 week of the baseline visit and unwillingness to limit calcium supplementation dosage to no more than 600 mg/day for the duration of the study.
7. Current use of medications or conditions (e.g. untreated celiac disease) that would interfere with absorption or metabolism of vitamin D.
8. Current use of medications approved by the FDA for weight management.
9. Use of thiazide diuretics at a total dose greater than 37.5 mg/day.
10. Use of anticonvulsant drug started within 6 months of screening. Stable regimen of anticonvulsants is allowed.
11. History of intolerance to vitamin D supplements.

Other Medical History

12. Severe symptomatic cardiovascular disease based on history and physical examination (unstable angina, dyspnea on exertion, paroxysmal nocturnal dyspnea, arrhythmia, congestive heart failure NYHA class II or higher, claudication)
13. History (past 1 year) of myocardial infarction, percutaneous coronary intervention or coronary artery bypass graft.
14. History (past 1 year) of cerebrovascular disease (stroke, transient ischemic attack).
15. Any type of cancer (past 5 years) except for basal cell skin cancer. Prostate cancer (for men over age 55) or well-differentiated thyroid cancer that are not expected to require treatment (except for suppression with thyroid hormone) over the next 4 years, are not exclusions.
16. History (past 6 months) of treatment with oral (for > 7 days) or intravenous glucocorticoids or disease likely to require oral or intravenous glucocorticoid therapy during the study (inhaled glucocorticoids are *not* excluded).
17. History (past 1 year) of substance abuse or unstable psychiatric disorder that in the opinion of the site investigator would impede competence or adherence with study procedures or hinder completion of the study or increase risk.
18. History of bariatric surgery (e.g. Roux-en-Y Gastric Bypass) or planned bariatric surgery in the next 3 years.
19. A life-threatening event within 30 days of screening or currently planned major surgery.
20. Any other unstable active medical condition (including but not limited to liver disease, wasting illness, AIDS, tuberculosis, oxygen-dependent

	chronic obstructive pulmonary disease, organ transplant, Cushing's syndrome) that in the opinion of the site investigators would impede competence or adherence with study procedures or increase risk. 21. Uncontrolled hypertension (systolic blood pressure > 160 mm Hg or diastolic blood pressure > 100 mm Hg). 22. Poor venous access. <i>Laboratory Evaluation</i> 23. Serum liver transaminase higher than 3 times the normal range for the clinical site's laboratory 24. Anemia (hematocrit < 32 for women, < 36 for men), transfusion (within 6 months of screening or chronic requirement), blood donation (within 3 months of screening) or other condition (hemolysis, hemoglobinopathy) rendering HbA1c results unreliable as indicator of chronic glycemia. Transfusion or blood donation does not exclude participant 25. Low platelet count (< 50,000). 26. Chronic kidney disease, defined as estimated glomerular filtration rate [GFR] < 50 mL/min per 1.73m² from creatinine level measured at the clinical site's laboratory and GFR calculated centrally. 27. Hypercalcemia, defined as serum calcium concentration greater than the upper limit of normal, measured at the clinical site's laboratory. 28. Hypercalciuria, defined as spot urine (morning void) calcium-creatinine ratio > 0.275. <i>Other</i> 29. Participation (within 30 days of screening) in another interventional research study. 30. Previous randomization in the D2d study. Participants who did not qualify after screening may be screened again if the prior reason for exclusion has been addressed (e.g. high blood pressure is treated). 31. Any other reason that in the opinion of the site investigator would impede adherence with study procedures or hinder completion of the study or increase risk. <i>Women only</i> 32. Pregnancy (past 1 year by report or positive pregnancy test at screening), intent to become pregnant in the next 4 years or unprotected intercourse. History of gestational diabetes is <i>not</i> an exclusion criterion. 33. Currently breastfeeding. 34. Use of oral contraceptives started within 3 months of baseline. Stable regimen of oral contraceptives or any other hormonal method of contraception (e.g. implantable) is allowed.
<i>Environment</i>	U.S. based research centers representative of the population at risk for both vitamin D insufficiency/deficiency and diabetes.
<i>Recruitment Strategy</i>	
<i>Prescreening</i>	-Site-specific based on what has worked well at each participating site.
<i>Screening</i>	-Medical examination, fasting labs (fasting plasma glucose, hemoglobin

<i>Recruitment Period</i>	A1c, safety labs). -75-gram oral glucose tolerance test will be done at baseline. -Approximately 2 years
<i>Study Duration</i>	-Four years; average participant follow-up will be ~3 years.
<i>Visits</i>	-Twelve scheduled visits: Screening, Baseline (BAS), Randomization (RAD), M03, M06, M12, M18, M24, M30, M36, M42 and M48. Additional visits may be required for confirmatory glycemic testing or safety evaluation.
<i>Phone calls</i>	-Seven scheduled telephone calls in between visits: M09, M15, M21, M27, M33, M39, and M45.
<i>Primary Outcome</i>	Time to development of diabetes
<i>Secondary Outcomes</i>	-Variability of response to vitamin D supplementation by several baseline characteristics: (1) race (as a proxy for skin pigmentation); (2) ethnicity; (3) BMI; (4) waist circumference; (5) age; (6) geographic location (proxy for sun exposure); (7) 25OHD concentration. -HbA1c, FPG and 2hPG as continuous variables. -Insulin resistance and beta cell secretion (indices derived from the OGTT). -Plasma 25OHD concentration and determine phenotypic, including seasonal and geographic, characteristics associated with variability on achieved plasma 25OHD concentration. -Safety and tolerability of vitamin D supplementation.
<i>Sample Size (total)</i>	-2,382 participants randomized to vitamin D or placebo
<i>Participants per site</i>	-Variable, depending on site's experience (~100 to 150 per site)
<i>Attrition rate</i>	-15% (maximum) of the original cohort over the 4-year study period
<i>Analysis Strategy</i>	Kaplan-Meier estimates of "time to confirmed diabetes" distributions will be calculated for each treatment group. The log-rank test will then be used to perform an adjusted comparison of the time-to-event distributions in the two treatment groups. Cox proportional hazard models will be used to calculate an estimate of the adjusted hazard ratio. Pre-specified subgroup analyses will be performed in participant subgroups defined by baseline variables, to gain information on predictors of response to therapy

FFQ, food frequency questionnaire; M=month since baseline; L= laboratory analysis is performed at the clinical site's (local) laboratory, C= laboratory analysis is performed at the central laboratory; CBC, complete blood count includes white blood cell count without differential, hemoglobin & hematocrit and platelet count; LFT, liver function tests (AST, ALT); GFR, estimated glomerular filtration rate; OGTT, 75-gram oral glucose tolerance test; Glu₃₀ plasma glucose 30 minutes after 75 gram glucose load during OGTT; FPG, fasting plasma glucose; HbA1c, hemoglobin A1c; 2hPG, plasma glucose at 2 hours after a 75-gram glucose load during OGTT.

1. Prior to formal screening, there will be a site-specific pre-screening phase (e.g. contact over the phone or via the web). Pre-screening phase may also include an additional visit.
2. Complete medical history and physical examination will be done at screening.
3. Interim medical history will be done at all follow-up visits.
4. Symptom-directed specific physical examination will be done as needed if adverse events are reported at follow-up visits.
5. Vital signs include height, weight, blood pressure and heart rate.
6. Food frequency questionnaire (FFQ) will be completed at baseline, M12 and M36 in participants free of diabetes.
7. Lifestyle counseling includes educational material at baseline. During the trial, participants will join the D2d Support and Education Program.
8. All laboratory and urine testing is done after 8 hours of overnight fasting.
9. Pregnancy test is required for women of reproductive potential at baseline. Point-of-care urine testing will be done followed by confirmatory blood testing, if point-of-care test is positive. If point-of-care urine testing is not an option, a urine or serum test will be done at the site's laboratory. Pregnancy testing is done during the study if the participant reports missing two consecutive menstrual periods.

10. Safety labs (serum calcium, creatinine [GFR] and the urine calcium-creatinine ratio) will not be performed after a participant has reached the primary outcome of diabetes.
11. HbA1c, FPG, 2hPG and urine calcium-creatinine ratio are measured and reported to sites in real time. All other laboratory tests are done at a later time and not reported to the sites.
12. 2hPG, Glu₃₀, and insulin (Ins₀, Ins₃₀, Ins₁₂₀) will be performed at baseline, and at the annual visits in all participants free of diabetes.
13. Semi-annual confirmatory testing: If FPG ≥ 126 or HbA1c $\geq 6.5\%$ at the semi-annual visit, a confirmatory visit will be conducted and only the abnormal test will be repeated.
14. Annual confirmatory testing: If FPG ≥ 126 or HbA1c $\geq 6.5\%$ or 2hPG ≥ 200 mg/dL at the annual visit, a confirmatory visit will be conducted that may include an OGTT (see text for details).
15. Letter informing participant's physician(s) of his/her patient's participation in the D2d study.
16. Letter informing participant's physician(s) of diabetes diagnosis according to the study's criteria.

2. BACKGROUND, RATIONALE AND SIGNIFICANCE

2.1 Background and Rationale

The incidence of diabetes is increasing at an alarming rate both nationally and worldwide with 1.9 million new cases diagnosed in 2010 in the US alone,¹ with nearly 9 out of 10 new cases due to type 2 diabetes. The diabetes population and related costs are expected to more than double in the next quarter century,² as more than 79 million Americans are at risk of developing diabetes.^{1,3,4} In clinical trials, lifestyle changes aiming at weight loss are successful at reducing risk of diabetes.⁵⁻⁹ However, long-term weight-maintenance in the clinical setting has proved elusive. Moreover, even after successful weight loss, substantial residual risk (~40-50%) remains and may be attributable to modifiable factors.¹⁰ Several medications that are used to treat established diabetes have also been studied for prevention of diabetes and many have been shown to delay incident diabetes;^{9,11-17} however, the role of pharmacologic agents for prevention of diabetes is not clear.⁹ Therefore, identification of easily modifiable risk factors that are safe, inexpensive and acceptable is urgently needed to prevent type 2 diabetes and decrease disease burden.

Based on recent evidence,¹⁸⁻⁴⁴ which has been synthesized in systematic reviews,⁴⁵⁻⁴⁸ suboptimal vitamin D status has emerged as a potential contributor to the pathophysiology of type 2 diabetes. However, the evidence to support general supplementation for prevention of type 2 diabetes does not currently exist because the favorable association between vitamin D status and type 2 diabetes risk is based almost exclusively on observational studies, which may be confounded by a variety of factors and there are no published trials specifically designed and powered to test the effects of vitamin D supplementation on the development of type 2 diabetes. The D2d study will test this hypothesis by examining the causal relationship between vitamin D and development of diabetes in persons at risk for diabetes. If the hypothesis of a link between vitamin D and type 2 diabetes is confirmed by the proposed trial, the results will have significant public health implications since vitamin D status has declined in the US over the last decade⁴⁹ and vitamin D supplementation can be implemented easily and inexpensively in clinical practice.

2.2 Biologic plausibility of an association between vitamin D and type 2 diabetes

When glucose intolerance and type 2 diabetes develop, impaired pancreatic beta-cell function, insulin resistance and systemic inflammation are often present.^{50,51} There is evidence that vitamin D influences these mechanisms, as described next.

Vitamin D and pancreatic beta-cell function / insulin secretion

In *in vitro* and *in vivo* studies, vitamin D deficiency impairs glucose-mediated insulin secretion from beta-cells,⁵²⁻⁵⁵ while vitamin D supplementation restores insulin secretion.^{52,54-57} Vitamin D may have a direct effect on beta-cell function mediated by binding of the circulating active form, 1,25(OH)₂D, to the vitamin D receptor, which is expressed in pancreatic beta-cells.^{58,59} Furthermore, mice lacking a functional vitamin D receptor show impaired insulin secretory response following a glucose load, attributed to a decrease in insulin synthesis resulting in a reduction in the amount of insulin stored in the beta cell.⁵⁸ The presence of the vitamin D response element in the human insulin gene promoter⁶⁰ and transcriptional activation of the human insulin gene by 1,25(OH)₂D⁶¹ further support a direct effect of vitamin D on insulin synthesis and secretion. Alternatively, activation of vitamin D also occurs within the pancreatic beta cell by the 25-hydroxyvitamin D-1 α -hydroxylase enzyme (CYP27B1), which is expressed in pancreatic beta cells.⁶² Such a mechanism allows for a paracrine effect of circulating 25OHD. An indirect effect of vitamin D on the beta cell may be mediated via its regulation of extracellular calcium concentration and calcium flux through the beta cell.⁶³ Insulin secretion is a calcium dependent process,⁶⁴ therefore, alterations in calcium flux can have an effect on insulin

secretion.⁶⁵⁻⁶⁷ Vitamin D also regulates calbindin, a cytosolic calcium-binding protein found in many tissues including beta cells.^{59,68} Calbindin is a modulator of depolarization-stimulated insulin release via regulation of intracellular calcium.⁶⁹ Finally, vitamin D may promote beta-cell survival by modulating the generation (e.g. through inactivation of nuclear factor-kB [NF-kB]) and effects of cytokines.^{70,71} In some but not all cross-sectional human studies, an association between the blood 25OHD concentration and insulin secretion has been reported.^{72,73,74}

Vitamin D and insulin sensitivity

In peripheral insulin-target cells, vitamin D may enhance insulin sensitivity in several ways. Vitamin D may directly augment insulin sensitivity by stimulating the expression of insulin receptors.^{60,61,75,76} The active form, 1,25(OH)₂D, enters insulin-responsive cells and interacts with the vitamin D receptor, activates the vitamin D receptor-retinoic acid X-receptor (RXR) complex which, in turn, binds to a vitamin D response element found in the human insulin receptor gene promoter. The result is enhanced transcriptional activation of the insulin receptor gene, which increases the total insulin receptor number without altering receptor affinity. Vitamin D may also enhance insulin sensitivity by activating peroxisome proliferator-activated receptor delta (PPAR-δ), a transcription factor implicated in the regulation of fatty acid metabolism in skeletal muscle and adipose tissue.⁷⁷ An indirect effect of 1,25(OH)₂D on insulin sensitivity might also be exerted via its important and well-recognized role in regulating extracellular calcium concentration and flux through cell membranes. Calcium is known to be essential for insulin-mediated intracellular processes in insulin-responsive tissues such as skeletal muscle and adipose tissue,^{78,79} with a very narrow range of intracellular calcium needed for optimal insulin-mediated functions.⁸⁰ Changes in intracellular calcium in insulin target tissues may contribute to peripheral insulin resistance⁸⁰⁻⁸⁷ via impaired insulin signal transduction^{87,88} leading to decreased glucose transporter activity.⁸⁷⁻⁸⁹ Hypovitaminosis D also leads to increased parathyroid hormone concentration, which has been associated with increased insulin resistance.^{90,91} Vitamin D may also affect insulin resistance indirectly through the renin-angiotensin-aldosterone system.⁹²⁻⁹⁵ Finally, vitamin D insufficiency is associated with increased fat infiltration in skeletal muscle, independent of body mass, which is thought to contribute to decreased insulin action.⁹⁶ In observational human studies, low vitamin D status (assessed by self-reported vitamin D intake or blood 25OHD concentration) has been associated with simple indices of insulin resistance, including measurements of fasting insulin and homeostasis model assessment (HOMA-IR),^{20,29,35,72,73,97-101} but the association is not consistent.^{74,99,102}

Vitamin D and systemic inflammation

Systemic inflammation, via an increase in pro-inflammatory cytokines, plays an important role in the pathogenesis of type 2 diabetes, mostly by promoting insulin resistance; however, pancreatic beta cell function may also be affected via cytokine-induced apoptosis.^{50,103-105} Vitamin D can lessen the effects of systemic inflammation on type 2 diabetes risk in several ways. For example, 1,25(OH)₂D may improve insulin sensitivity and protect against beta cell cytokine-induced apoptosis by directly modulating the expression and activity of cytokines.^{71,106-108} One such pathway may be through down-regulation of NF-kB, which is a major transcription factor for TNF-α and other inflammatory mediators.¹⁰⁹ Another pathway that may, at least in part, mediate the anti-apoptotic effect of 1,25(OH)₂D on beta cell is through counteracting cytokine-induced Fas expression.¹¹⁰ Several other immune-modulating effects of 1,25(OH)₂D (e.g. blockade of dendritic cell differentiation, inhibition of lymphocyte proliferation, inhibition of foam cell formation and cholesterol uptake in macrophages, enhanced regulatory T-lymphocyte development)^{107,111} may provide additional pathways of protection against inflammation-induced type 2 diabetes risk. In observational human studies, low vitamin D status (assessed by self-reported vitamin D intake or blood 25OHD concentration) has been associated with elevated concentration of markers of systemic inflammation in some^{101,112,113} but not all studies.^{20,114-116}

2.3 Evidence from human studies for a link between vitamin D and type 2 diabetes

Observational Studies

The strong data in humans that link vitamin D to type 2 diabetes are primarily from observational studies. Cross-sectional studies have generally reported inverse associations between vitamin D status and prevalent hyperglycemia.^{35,38,40,41,45,73,97,99,117-131} In a large cross-sectional study with data from the U.S. based National Health Nutrition Examination Survey (NHANES), serum 25OHD concentration was inversely associated with prevalence of diabetes in a dose-dependent pattern in non-Hispanic whites and Mexican-Americans, after multivariate adjustment, including BMI.⁹⁷ In this study, there was no association in non-Hispanic blacks despite lower 25OHD concentration found in this racial group, which may be explained by the observation that non-whites exhibit a different vitamin D, calcium and PTH homeostasis compared to whites.¹³² However, a subsequent analysis from NHANES did not find an interaction between blood 25OHD concentration and race or ethnicity on glycemic outcomes.³⁵ More recent studies using NHANES data have repeatedly confirmed the inverse association between 25OHD and glycemia,^{35,121,133-135} which has also been reported in other large cohorts from the U.S.⁹¹, Europe¹³⁶ and China.¹⁰⁰ Cross-sectional studies, however, are difficult to interpret, as the directionality of the association cannot be determined.

To overcome the inability of cross-sectional studies to establish the direction of the causality between vitamin D status and type 2 diabetes related parameters, longitudinal observational studies have been conducted where vitamin D status is assessed prior to the development of the outcome of interest, incident type 2 diabetes. There are 14 studies (from 15 cohorts) that have reported on the longitudinal association between vitamin D status (intake or 25OHD) and risk of type 2 diabetes.^{18,21,22,25,26,28,36,37,39,42-44,137} Nearly all of them have reported an inverse association between vitamin D status (intake or 25OHD concentration) and incident type 2 diabetes. A recent meta-analysis, examining only 25OHD concentration as the predictor (Song et al, under review),⁴⁸ identified 9 publications that provided data from 13 cohorts involving 65,721 participants and 3,567 incident cases of diabetes.^{22,25,28,37,39,42-44,137} Comparing the highest to the lowest category of 25OHD, the pooled relative risk for incident diabetes was 0.65 (95% CI, 0.55-0.77). A linear trend meta-regression analysis showed that each 4 ng/mL increment in 25OHD was related to a 4% lower risk.

Intervention Studies

Several trials have reported the effect of vitamin D supplementation on glycemia^{19,34,138-146} or incident diabetes by self-report. In nine trials that included participants with *normal glucose tolerance*, supplementation with vitamin D had overall a neutral effect on glycemic measures or incident diabetes.^{19,34,138,140,141,143,144,147,148} However, several of these trials were designed for non-glycemic outcomes and the analyses on diabetes were *post-hoc* and *all trials* (except for the Women's Health Initiative trial, WHI) *were underpowered for glycemic outcomes*. In several trials, adherence with supplementation was suboptimal. For example, in a post-hoc analysis of the RECORD trial (a community-based trial designed for bone outcomes),¹⁴⁷ 800 IU/day of vitamin D₃ did not change risk of *self-reported type 2 diabetes*; however, among study participants who were highly compliant with supplementation, there was a notable trend towards reduction in type 2 diabetes risk with vitamin D₃ (odds ratio 0.68; 95%CI 0.40, 1.16), which *highlights the importance of efficacy vs. effectiveness trials*. Importantly, several trials supplemented with infrequent (weekly or monthly) large doses of vitamin D, a commonly used clinical approach, which may not be a desirable physiologic method for supplementation and may be counterproductive.¹⁴⁹

The potential effect of vitamin D appears to be more prominent among persons with pre-diabetes. In a post-hoc subgroup analysis conducted using data from a completed trial designed for fractures, combined vitamin D₃ (700 IU/day) and calcium carbonate (500 mg/day) supplementation improved fasting plasma glucose (FPG) and insulin resistance (HOMA-IR) among adults with glucose

intolerance at baseline,¹⁹ suggesting that *vitamin D may benefit only individuals at high risk (e.g. pre-diabetes)*. In this study, *the reduction in FPG over 3-years was similar to the reduction in FPG achieved with metformin or lifestyle, in the Diabetes Prevention Program, which was associated with a 31-58% decrease in incident diabetes.*⁵ In the Calcium and Vitamin D for type 2 Diabetes Mellitus (CaDDM) study, a 2x2 factorial design trial, vitamin D supplementation improved - disposition index, a composite measure of beta cell function that accounts for the prevailing insulin sensitivity, in participants with pre-diabetes but without regard to baseline vitamin D status or calcium supplementation.²⁴ In another intervention study, very similar to the CaDDM trial, where vitamin D was given without a placebo, insulin sensitivity improved after 4 weeks of vitamin D administration in persons with pre-diabetes.¹⁵⁰ *On the basis of these observations, in the proposed D2D trial, a pre-diabetes population is targeted.*

2.3 Summary of human studies

Although the data from published studies suggest a strong link between vitamin D and diabetes risk, the evidence to support general supplementation with vitamin D for diabetes prevention does not currently exist. The evidence is based almost exclusively on observational studies, which may be confounded by many factors and there are no published trials designed and powered to test the effects of vitamin D supplementation on reducing diabetes risk; therefore, definitive conclusions cannot be drawn on the role of vitamin D for prevention of type 2 diabetes. There have been numerous previous occasions where highly encouraging data from observational studies led to irrational exuberance and widespread adoption of the intervention which proved premature, as subsequent trials did not confirm benefit (e.g. hormone therapy, vitamin E).¹⁵¹⁻¹⁵⁷ A trial - such as the D2d study - is therefore needed to address the issue of causality and quantify the protective benefit of vitamin D in type 2 diabetes risk, if present, in a target population most likely to benefit.

2.4 Potential impact on human health

The “excitement” surrounding the role of vitamin D for diabetes, and other chronic diseases, has led to dramatic increases in 25OHD assays done as part of routine medical care and in supplementation with very high doses of vitamin D to “improve” vitamin D status. Medicare payments for vitamin D testing nearly quadrupled between a 2-year span, 2006 and 2008, to \$129 million. A decade ago, these payments were only about \$1 million. Concurrently, spending on vitamin D supplements has increased tenfold in the last 8 years to \$425 million in 2009, which represents a growth of 81% from 2008.¹⁵⁸ Manufacturers of vitamin D assays and supplements have rushed to claim a piece of the “vitamin pie;” however, such enthusiasm is premature as the evidence is extrapolated from observational studies, which are severely limited, as outlined above. Furthermore, simply raising 25OHD level does not always translate to favorable outcomes.^{149,159}

The need for such a trial has been recognized in the recent literature in editorials, reviews and book chapters.^{32,46,47,147,160-183} Of importance, the 2011 Institute of Medicine report on dietary reference intakes (DRI) for calcium and vitamin D recognized as a major limitation in setting the DRI the lack of long-term trials with vitamin D supplementation, and *identified diabetes as one of the most promising non-skeletal areas that require further research with rigorously done trials to confirm the promising results seen in observational and mechanistic studies.*¹⁸⁴ The Endocrine Society guidelines also note that “trials that evaluate the effects of vitamin D doses in the range of 2000 to 5000 IU/day on non-calcemic health outcomes are desperately needed.”¹⁷⁵

The proposed trial, therefore, addresses an important and timely question and has the potential for significant impact in the clinically important areas of vitamin D and type 2 diabetes prevention with extensive public health implications especially given that the cost of supplementation with vitamin D is inexpensive compared to treating the chronic disease and its complications. We expect the D2d study results to define the role of vitamin D supplementation in modifying type 2 diabetes risk. If the

trial confirms a favorable benefit/harm ratio of raising 25OHD in pre-diabetes, then vitamin D supplementation will be integrated into conventional medical approaches to prevent type 2 diabetes and ameliorate personal and societal disease burden in this high-risk population. Moreover, the study will define subgroups that may benefit preferentially from optimizing vitamin D status (e.g. obese vs. non-obese, white vs. non-white). The study can also serve as the backbone for ancillary analyses to meet mechanistic and related research needs identified by the NIH and others.

3. HYPOTHESES AND SPECIFIC AIMS

3.1 Study Objectives

The *objectives* of the D2d study are to evaluate the safety of oral daily vitamin D supplementation and its effect on the time to onset of clinical diabetes in participants with pre-diabetes (at risk for type 2 diabetes).

3.2 Specific Aims

3.2.1 Primary Specific Aim

The *primary aim* of the study is to assess whether, in participants with pre-diabetes, oral daily vitamin D₃ supplementation reduces the rate of progression from pre-diabetes to clinical diabetes. The underlying hypothesis is that, compared to placebo, vitamin D₃ supplementation will reduce the rate of incident diabetes.

3.2.2 Secondary Specific Aims

Secondary specific aims will assess:

- Variability of response to vitamin D supplementation in subgroups defined by baseline characteristics: (1) race and ethnicity (as a proxy for skin pigmentation),¹⁸⁵ (2) BMI; (3) waist circumference,^{186,187} (4) age; (5) geographic location (proxy for sun exposure); (6) calcium intake (based on Food Frequency Questionnaire) 25OHD concentration.
- Effect of vitamin D supplementation on HbA1c, FPG and 2hPG as continuous variables.
- Effect of vitamin D supplementation on insulin resistance and beta cell secretion (indices derived from the OGTT).
- Effect of vitamin D supplementation on plasma 25OHD concentration and determine phenotypic, including seasonal and geographic, characteristics associated with variability on achieved plasma 25OHD concentration.
- Effect of vitamin D supplementation on blood pressure.
- Safety and tolerability of vitamin D supplementation.

3.2.3 Ancillary Studies

Other outcomes (e.g. effect of vitamin D supplementation on cardiovascular risk factors [cholesterol profile, C-reactive protein, urine albumin excretion]), as part of distinct ancillary studies requesting additional funds, may be developed in parallel. Additional blood (serum and plasma) and urine samples will be collected at the baseline, 6-month and annual visits for banking. These samples will become available to ancillary studies. After the D2d study is completed, long-term storage of blood and urine samples will be transitioned to the NIDDK Repository. In addition, at baseline, the study will collect whole blood for future DNA extraction, which may be done as part of a genetic ancillary study.

4. STUDY DESIGN, INTERVENTION AND PROCEDURES

4.1 Overview of Study Design

The D2d study is a multicenter, randomized (1:1), double-masked, placebo-controlled, parallel-group primary prevention clinical trial with 2 arms (oral daily vitamin D₃ vs. placebo) in participants at high risk for diabetes (with pre-diabetes) who will be followed for up to 4 years (mean ~3 years) after randomization for incident diabetes (Figure 4.1).

Adults at increased risk for type 2 diabetes (*pre-diabetes*), defined as meeting two-out-of-three ADA glycemic criteria established in 2010 (FPG 100-125 mg/dL or 2hPG 140-199 mg/dL or HbA1c 5.7-6.4%), will be randomized to receive, once daily, either a single soft-gel of vitamin D₃ (cholecalciferol, 4,000 IU) or matching placebo. Study participants will be seen every 3 months during the first 6 months and every 6 months for the remainder of the study. At the midpoint of each 6-month interval after the month 6 visit, participants will receive a telephone call to encourage compliance, assess for adverse events and receive a reminder of their upcoming visit. The primary outcome will be *time to diabetes*, defined by laboratory criteria derived from a 75-gram OGTT [to obtain 2hPG] done annually, FPG and HbA1c done every 6 months or when symptoms consistent with hyperglycemia are reported (Figure 9.1).

Figure 4.1. Schematic of Study Design

4.2 Performance Locations

The D2d trial will be conducted at multiple collaborating clinical sites in the United States. To ensure study representation of the US population, several sites are located at high latitude (to capture low UVB exposure) while other sites have high proportion of minority populations.

4.3 Principles Guiding Selection of Specific Intervention and Study Duration

4.3.1 Choice of Specific Vitamin D Supplementation as the Active Intervention

4.3.1.1 Choice of Vitamin D Formulation

Cholecalciferol (vitamin D₃, inactive form) was chosen instead of 1,25(OH)₂D (active form) because administration of the latter would increase risk of hypercalcemia. Moreover, certain critical tissues, such as the beta cell, express 1-alpha-hydroxylase (CYP27B1) and can convert inactive vitamin D to its active metabolite.⁶² Cholecalciferol (D₃) was chosen over ergocalciferol (D₂) because supplementation with D₃ may result in a greater and sustained increase in 25OHD level and because at high doses, D₂ may be less effective than D₃.^{184,188-192} Lastly, vitamin D₃ is the most commonly consumed vitamin D form; therefore, use of vitamin D₃ will increase the study's translational potential.

4.3.1.2 Choice of Vitamin D Dose (amount and frequency)

Rationale for amount of vitamin D. Based on the available literature, the planning committee has determined that the selected dose of 4,000 IU/day for vitamin D provides the best possible balance of safety and efficacy in terms of obtaining a large-enough difference in 25OHD concentration between active and placebo groups and reaching a high enough 25OHD that will have an effect on the outcome of interest, as described below.

Based on published observational and short-term mechanistic intervention studies,^{18-22,27,28,34,45,47,193} it appears that a plasma 25OHD concentration of approximately 30-50 ng/mL is required to detect a protective effect of vitamin D in relation to type 2 diabetes, if present. In an observational study in the Nurses' Health Study, the median 25OHD in the highest quartile, which was associated with an approximate 50% risk reduction in incident type 2 diabetes, was 33 ng/mL.²² This level was consistent with another observational study by Knekt et al (mean 25OHD in the highest quartile, 30 ng/mL).^{27,28} Of particular relevance to the D2d trial, in a longitudinal observational study in the Diabetes Prevention Program (DPP) cohort, participants with pre-diabetes with baseline plasma 25OHD $\geq$ 30 ng/mL had a 28% risk reduction in incident diabetes over a 3-year period, after adjustment for the DPP lifestyle intervention, while participants with 25OHD concentration $\geq$ 50 ng/mL had a 56% risk reduction.²⁵ In the Stockholm Diabetes Prevention Program, progression from pre-diabetes to type 2 diabetes was reduced by 62% among those with 25OHD $>$ 28 ng/mL compared to those with 25OHD $<$ 18 ng/mL.¹⁹⁴ In a recent meta-analysis, the pooled relative risk of type 2 diabetes comparing the highest with the lowest quartile of 25OHD was 0.59 (0.52, 0.67), with little heterogeneity between the 11 studies included (3,612 cases and 55,713 non-cases).¹⁹⁵ In another meta-analysis (Song et al, under review),⁴⁸ 9 publications were identified that provided data from 13 independent cohorts involving 65,721 participants and 3,567 incident cases of diabetes.^{22,25,28,37,39,42-44,137} Comparing the highest to the lowest category of 25OHD levels, the pooled relative risk for incident diabetes was 0.65 (95% CI, 0.55-0.77). A linear trend meta-regression analysis showed that each 4 ng/mL increment in 25OHD levels was related to a 4% lower risk.⁴⁸ In the CaDDM trial, among participants with pre-diabetes (which is the target population in the D2d study), daily supplementation with 2,000 IU of vitamin D₃ achieved a mean 25OHD concentration of 31 ng/mL in the active arm, which was associated with improvements in beta cell function (disposition index) by approximately 40% and glycemia (HbA1c) by approximately 50% after 4 months.²⁴ In a six-month trial by von Hurst et al, insulin resistance with vitamin D supplementation improved the most when end-of-study 25OHD concentration was higher than 32 ng/mL.³⁴ Although one can extrapolate these data to recommend a much higher target 25OHD concentration, there is very limited longitudinal observational data²⁵ and no intervention studies to support targeting much higher levels.

Study participants, who will be overweight/obese and in many cases non-Caucasian, are expected to have a mean 25OHD concentration of approximately 20 ng/mL at study entry.^{19,22,24,49,196-199} Approximately 4,000 IU/day of vitamin D will be needed to increase participants' mean 25OHD to 35-40 ng/mL, especially during the winter.^{24,196,199-204} Of high relevance and importance to the D2d trial, in the CaDDM trial a dose of 2,000 IU/day of vitamin D₃ over 4 months achieved a mean 25OHD concentration of 31 ng/mL in a cohort of participants with pre-diabetes, which is identical to the target population in the D2d trial. The results from the CaDDM trial are in line with studies by Vieth et al,¹⁹⁹ Aloia et al²⁰² and Talwar et al where a daily vitamin D₃ dose of between 3,800 and 5,000 IU raised 25OHD above 30 ng/mL in all participants studied, including African American women. A recent dose response vitamin D supplementation study confirmed that 4,000 IU/day is an appropriate dose to raise 25OHD to $\sim$ 40 ng/mL in white post-menopausal women including those with obesity.²⁰⁴ Of note, the 2011 Institute of Medicine set the Tolerable Upper Intake Level (UL) of Vitamin D for adults at 4,000 IU/day.¹⁸⁴ The UL is defined as the highest level of daily nutrient intake that is likely to pose no risk of adverse health effects to almost all individuals in the general population; however, the report also emphasized that the "UL is not specified as an 'upper limit' for clinical research and it may be appropriate to conduct clinical research with doses exceeding the UL, as long as there is monitoring

and the protocol is carefully considered.” Vitamin D-related acute toxicity is not expected; however, the study will carefully assess and adjudicate all serious adverse effects reported by participants to gain insight into any potential risk of higher-dose vitamin D supplementation than that recommended by the Institute of Medicine for the majority of the healthy population, as described below.

Based on these arguments, the chosen dose balances efficacy (i.e. very likely to reach optimal 25OHD concentration that differentiates intervention from placebo) with safety.

Rationale for daily dose. Raising 25OHD can be achieved equally well with daily, weekly, or monthly vitamin D supplementation.^{201,205} Although non-daily dosing (e.g. weekly, monthly) is convenient and would reduce costs related of manufacturing, shipping, storage and distribution of study pills, the planning committee decided to test daily dosing because: (1) it is physiological in terms of how vitamin D exposure occurs and may be more likely to have an effect compared to infrequent and/or lower doses;^{149,159,184,206,207} (2) there is evidence that high infrequent (i.e. non-daily) doses of vitamin D may be metabolized differently as compared to daily doses and may provide either no benefit or result in an unfavorable benefit/risk ratio;^{149,159,184,206-210} (3) it is straightforward to apply among all sites; (4) it will maximize the trial's external validity.

4.3.1.3 Rationale for Lack of a Target 25OHD Concentration

The D2d study is designed so that most participants reach adequate plasma 25OHD concentration with adequate differentiation between the 2 study arms. A supplementation strategy that aims for a specific 25OHD threshold will not be used for the following reasons: (1) although 25OHD is a well-established biomarker of total vitamin D exposure (from intake and biosynthesis), it is not a validated health outcome surrogate i.e., simply aiming for a specific 25OHD threshold may not translate to favorable outcomes.^{149,184} The study will test for such thresholds in the planned mediation analyses. (2) Aiming for and achieving a specific 25OHD level is complicated, as it depends on a variety of contributing factors (e.g. baseline 25OHD, age, BMI, genetic predictors [gender, skin color, genetic polymorphisms], dietary and environmental factors). (3) The approach to not target a specific 25OHD concentration is practical and will increase generalizability of results. (4) Aiming for a specific 25OHD target would add significant expense and burden without proportional benefit.

4.3.2 Choice of Comparison Group

Selecting a comparison group is challenging for trials with vitamin D given the evolving nature of the evidence. The following ethical and scientific principles were considered to select an appropriate control: (1) From a “subject protection” point of view, control participants should be allowed to receive the “standard-of-care” vitamin D intake. For bone-related health, there are recent age-specific recommendations for vitamin D intake set by the Institute of Medicine and these will be included in the overall recommendations provided to all participants (see below).¹⁸⁴ *Notably, in relation to the outcome of interest (diabetes), there are no recommendations for vitamin D intake.*^{184,211} (2) Exclusively on the basis of observational studies, several investigators advise routine intake of doses higher than the Institute of Medicine recommended doses. However, such recommendations are not based on results from randomized controlled trials, which is the premise behind the D2d trial. Indeed, the current knowledge with vitamin D in relation to type 2 diabetes, but also for many other outcomes, is similar to other interventions (e.g. hormone replacement therapy, vitamin E)^{151-153,157,212-216} that were strongly supported by observational studies. Several investigators had even questioned the need for trials to test these interventions; however, when prospective controlled trials were completed, these interventions showed harm or no benefit, a result with a direct impact on clinical care. After taking these issues into consideration, the planning committee concluded that *all participants will be advised to follow* the Recommended Dietary Allowance (RDA) for vitamin D, which is 600 (up to age 71) or 800 IU/day (age 71 and older).¹⁸⁴ The RDA is the intake that meets or exceeds the requirements for 97.5 percent of the population. The control participants will be given a true placebo, instead of

supplying them with their IOM age-recommended level of vitamin D intake, as the latter would complicate the study design and increase cost. The study will not ask participants to specifically avoid sun, but will provide recommendations for sensible sun exposure.

The decision to use a true placebo: (1) balances all competing factors; (2) is consistent with current practice; (3) does not compromise participants' health; (4) favors adequate differentiation in 25OHD concentration between active and placebo arms; and (5) is consistent with the principle of 'equipoise' in relation to the underlying hypothesis.

4.3.3 Rationale for no randomization to calcium

A potential mechanism for the effect of vitamin D on t2DM risk may be indirect, via optimizing calcium status; however, the D2d study will not randomize to calcium supplementation because: (1) results from the CaDDM trial (Section 1.c.1) showed no effect of calcium supplementation alone and there was no interaction between vitamin D and calcium on outcomes;²⁴ (2) there is no evidence that high calcium alone improves t2DM related outcomes;^{36,39,217-219} (3) there is concern that calcium supplementation may increase risk of cardiovascular events;²²⁰⁻²²² (4) unlike vitamin D, calcium intake in the U.S. (~700-1000 mg/day) is closer to the current recommended levels^{18,184,223-225} and (5) adding a calcium pill may decrease adherence and increase gastrointestinal side effects, hypercalciuria and nephrolithiasis.²²⁶ All participants will receive written information describing the latest recommendations by the Institute of Medicine for calcium intake, as described below.

4.3.4 Case for Permitting Supplements Outside of the Study

Based on NHANES data, the average intake of vitamin D in the D2d target age group was approximately 400 IU/day, including from diet and supplements. The study will encourage all participants to optimize their dietary vitamin D intake and supplement their intake of vitamin D from supplements up to 600 or 800 IU per day (depending on their age); however, participants will be discouraged from taking vitamin D-containing supplements on their own throughout the trial, *beyond what is recommended by the Institute of Medicine for their age group (600 or 800 IU/day)*, unless specifically prescribed by a physician. The planning committee recognized that for practical reasons, participants may take up to 1000 IU/day of vitamin D on their own from all supplemental sources combined (stand-alone vitamin D supplements, multivitamins, medications containing vitamin D [e.g. Fosamax Plus D]), if they wish. The maximum allowable dose of 1000 IU/day was chosen because it is the dosage contained in many commercially available supplements and also commonly recommended by health care providers. Participants who are unwilling to limit outside-of-study vitamin D intake from supplements to 1000 IU/day for the duration of the study will be excluded from participating. During screening, potential participants who are taking more than the allowed vitamin D dose from supplements will be excluded from the study, unless they agree to lower their supplemental intake to no more than 1000 IU/day for 12 weeks prior to initiating the protocol and also agree not to exceed this supplemental threshold during the entire study.

Depending on the level of 25OHD threshold required to affect type 2 diabetes risk, it is plausible that allowing all participants to receive the age-appropriate Institute of Medicine recommended vitamin D intake may potentially reduce the study's ability to detect the effect of the intervention on diabetes; however, based on available data, the threshold for type 2 diabetes benefit, if present, appears to be no lower than 30-35 ng/mL (without an apparent plateau as 25OHD level increases), which we expect participants in the active group to achieve, while very few in the placebo group will do so, ensuring differentiation between the two arms in achieved 25OHD concentration. Finally, a potential challenge may be that participants will keep changing their vitamin D intake on their own during the study as more information about benefits/harms becomes available; however, this is currently much less likely to happen as the findings of the 2011 Institute of Medicine report, which have been disseminated

widely,^{184,206,227} call for only a moderate increase in intake of vitamin D compared to the previous guidelines.

Calcium Supplements: The Institute of Medicine recommendation for total (dietary and supplemental) calcium intake for adults is 1000-1200 mg/day from either food or supplements; however, there is concern that high calcium intakes from supplements may be associated with adverse cardiovascular effects and development of nephrolithiasis. The current recommendation is to optimize calcium intake through diet with supplementation only as needed to reach the recommended total intake. In the CaDDM trial, among persons with pre-diabetes – a population identical to the D2d trial – total calcium intake was 976 mg per day, nearly all of it coming from dietary sources (859 mg per day), which is consistent with calcium intake in the general population.^{18,184,223-225} Therefore, participants will not be allowed to take more than 600 mg/day of calcium on their own from all supplemental sources combined (e.g. stand-alone calcium supplements, multivitamins, medications containing calcium [e.g. Actonel with Calcium]), unless specifically prescribed by a physician. Participants who are unwilling to limit calcium supplementation to 600 mg/day for the duration of the study will be excluded from participating. During the pre-screening, potential participants who are reporting more than the allowed calcium intake from supplements will be excluded from the study, unless they agree to lower their supplemental intake to no more than 600 mg/day or less for 1 week prior to the screening visit and also agree not to exceed this supplemental threshold during the study.

Other supplements: Participants are free to take additional vitamins or supplements that do not contain vitamin D or calcium on their own. All supplement use (with or without vitamin D) will be recorded, based on self-report, at each visit.

4.3.5 Duration of Intervention and Follow-up Period

Participants will be followed for up to 4 years (average follow up of approximately 3 years) for development of the primary outcome, diabetes. There are no definitive data to determine the optimum duration of exposure to vitamin D required to affect diabetes risk. In an observational study in the Nurses' Health Study, women with the highest 25OHD concentration at baseline had a reduction in diabetes by 40% over an approximate 10-year follow-up period.²² In the Framingham Offspring Study, participants in the highest tertile of predicted 25OHD score had a 40% lower incidence of diabetes during a 6-year follow-up period.²¹ Of particular relevance to the D2d trial, in the Diabetes Prevention Program (DPP) cohort, participants with pre-diabetes who had a plasma 25OHD concentration ≥ 30 ng/mL at baseline had a 28% risk reduction in incident diabetes over a 3-year period, after adjustment for the DPP lifestyle intervention.²⁵ In the Stockholm Diabetes Prevention Program, among participants with pre-diabetes, the risk of progression to type 2 diabetes was reduced by 62% among those with blood 25OHD above 28 ng/mL compared to those with 25OHD lower than 18 ng/mL over a 8-year follow-up, which corresponds to a 23% reduction for each 4 ng/mL increase in blood 25OHD concentration.¹⁹⁴ These results are consistent with other observational cohorts.²⁶⁻²⁸ A post-hoc analysis of a completed trial showed a reduction of approximately 90% in FPG and insulin resistance (HOMA-IR) in participants with pre-diabetes after 3 years of supplementation with vitamin D.¹⁹ In the RECORD trial, a trend towards reduced diabetes risk was seen with vitamin D supplementation after 2-4 years of follow up.¹⁴⁷ In the CaDDM trial, among participants with pre-diabetes, 2,000 IU/day of vitamin D₃ improved measures of beta cell function (disposition index) by approximately 40% and glycemia (HbA1c) by approximately 50% after 4 months.²⁴ In addition to vitamin D-specific mechanisms, the planning committee also took into consideration additional issues, including practical ones, when deciding on the follow-up period, as follows: (1) a shorter follow-up period will minimize "study fatigue" by study personnel and participants, and will maximize retention; (2) a shorter follow-up period will allow the study to be completed faster and results disseminated to the scientific community and public earlier, although with a shorter follow-up period, more participants need to be recruited, to ensure sufficient statistical power; (3) adequate follow-up is required to allow progression to diabetes to occur; (4) supplementation is expected to achieve steady state level of plasma 25OHD

concentration within 4 months in the majority of participants,^{24,228-230} (4) the rate of progression from pre-diabetes to diabetes is expected to be about 10 per 100 person-years in the control arm, which is a rate high enough to allow for a statistical comparison with the active arm. After considering all these issues, an average follow up period of approximately 3 years was chosen, with early enrollees being followed for up to 4 years and the sample size was calculated accordingly.

Rationale for lack of run-in period. A run-in period before randomization could identify participants whose 25OHD concentration may not respond to vitamin D or develop side effects and also could identify participants that are likely to become low adherers, thereby increasing adherence to study medications and retention. However, a run-in period was not included in the study design because it would add considerable expense without proportional benefit as the proposed intervention and assessment of outcomes are relatively low-burden and vitamin D supplementation raises 25OHD concentration in all participants (although the degree of rise may vary). Furthermore, external validity may be lessened in studies that include a run-in period.²³¹

4.3.6 Advice on Lifestyle

Eligible participants are at increased risk for diabetes. In accordance with the latest ADA Standards of Care,²³² at baseline, the study will: (1) provide enrolled participants with written information on the current recommendations for prevention of type 2 diabetes, which emphasizes lifestyle intervention aiming to achieve and maintain at least a 5% weight loss and increased physical activity to at least 150 min/week of moderate activity;²³² (2) send a letter to participants' primary care providers indicating that participants are at risk for diabetes and to advocate efforts at weight loss and increasing physical activity. This approach is consistent with the lifestyle advice that was provided to participants in other type 2 diabetes prevention trials that have compared medications with placebo.^{11-13,16} Importantly, during the study, all participants will be invited to join the D2d Support and Education Program (SEP). As part of this program, participants will attend group meetings, held twice yearly at each site, to discuss specific topics in nutrition, exercise and diabetes (e.g. healthy eating strategies for the holidays). These meetings will allow the opportunity to meet other participants and will also serve as a way to enhance retention. The Recruitment and Retention subcommittee will suggest topics that the sites can utilize for these meetings. Finally, participants will receive a D2d study newsletter at regular intervals, which will include a section on healthy nutrition and exercise. Participants may lose some weight during the study, but this is not expected to confound the results as it is anticipated that weight change will be similar between arms.

4.3.7 Measurements of Other Exposures

Vitamin D status. Plasma 25OHD concentration will be measured as a proxy for vitamin D status at baseline and yearly during follow-up to assess the efficacy of the intervention in the active arm at improving vitamin D status and to evaluate for heterogeneity of treatment effect by achieved 25OHD concentration. *Self-reported vitamin D intake* will be estimated from a validated self-administered semi-quantitative food frequency questionnaire administered at baseline, month 12 and month 36 in participants free of diabetes.^{18,233-236}

Calcium status. There are no widely accepted measures of adequacy of calcium status. Calcium intake will be used as proxy of calcium adequacy at baseline and during the intervention. *Self-reported calcium intake* will be estimated from a validated food frequency questionnaire administered at baseline, month 12 and month 36 in participants free of diabetes.¹⁸

4.3.8 Principles Guiding Selection of Patient Population

Rationale for selection of a population with pre-diabetes. The study will recruit and follow participants with pre-diabetes. The target population was selected based on published data from post-hoc analyses of a completed trial designed for skeletal outcomes,¹⁹ which showed that vitamin D supplementation had a favorable effect on FPG and insulin resistance (HOMA-IR) only among participants with pre-diabetes at baseline. These findings were confirmed by results from the CaDDM trial among participants with pre-diabetes, which showed that oral vitamin D₃ supplementation (2,000 IU/day) improved the disposition index (a measure of beta cell function that accounts for the prevailing insulin sensitivity) and glycemia.²⁴ In contrast, other studies (most were underpowered) did not report an effect of vitamin D supplementation on glycemia among those with normal glucose tolerance or established diabetes.^{32,33,45,47,165} Therefore, the D2d study is focused on a population with pre-diabetes, which would be the most likely group to benefit from the proposed intervention.

The ADA guidelines define that a pre-diabetes state (“at increased risk for diabetes”) exists when a patient does not meet criteria for diabetes and meets one of the following criteria: FPG 100-125 mg/dL or 2hPG 140-199 mg/dL or HbA1c 5.7-6.4%.²³² The addition of HbA1c as a criterion for the diagnosis of pre-diabetes is expected to increase the number of patients diagnosed with pre-diabetes but may also identify patients at different risk compared to the definition using only the FPG or 2hPG criteria. *For the D2d trial, pre-diabetes is defined if 2-out-of-3 ADA glycemic criteria for pre-diabetes are met.* This definition was chosen to identify a population that is at somewhat higher risk for developing diabetes than when diabetes is defined by only 1-out-of-3 criteria. As a result, the D2d target population will: (1) potentially benefit the most from the proposed intervention and (2) have a higher conversion rate to clinical diabetes, thereby lowering the required sample size.

Rationale for chosen age range. The study will include participants equal to or older than 30 years. Risk for pre-diabetes increases with age but we chose a lower age than what is typically considered higher risk (>45 years), because lower age at diagnosis of pre-diabetes is associated with higher progression to diabetes.⁵ Also, this age cutoff would reduce “contamination” with type 1 diabetes or Latent Autoimmune Diabetes of Adults and minimize loss to follow-up due to social mobility. The planning committee selected no upper age limit to increase the generalizability of findings and to allow for heterogeneity of treatment effect (subgroup) analyses by age.

Rationale for chosen weight/body mass index range. The study will include participants with a BMI equal to or higher than 25 (23 kg/m² for Asians) but not higher than 40 kg/m² because overweight/obesity is a significant risk factor for type 2 diabetes and because those with severe obesity require much higher doses of vitamin D to achieve the desired 25OHD concentration.²³⁷

Rationale for lack of “low vitamin D status” as an inclusion criterion: Vitamin D status (assessed by blood 25OHD concentration) at baseline is not an inclusion criterion for the following reasons: (1) in small trials, vitamin D benefited those with pre-diabetes irrespective of baseline 25OHD concentration;^{19,24} (2) the definition of ‘optimal’ vitamin D status is controversial and no consensus exists on optimal blood 25OHD level,^{171,175,184,238-242} (3) suboptimal vitamin D status is widespread in the U.S. adult population, especially among overweight and obese persons;^{49,197,243-249} (4) to ensure that the study is as “pragmatic” as possible and results are generalizable to clinical practice;²⁵⁰ (5) baseline 25OHD is a treatment selection marker to enter the heterogeneity of treatment effect (subgroup) analyses and to assess its performance, participants with a wide range of 25OHD must be enrolled;²⁵¹ (6) 25OHD concentration varies by season,^{184,252} and may decrease during acute phase response;^{253,254} (7) screening with 25OHD would be cumbersome and expensive. All participants will be encouraged to take the IOM recommended dose of vitamin D for their age.

Other clinical characteristics: Study participants with pre-diabetes will have baseline clinical characteristics (age, gender, race, ethnicity, BMI) representative of the U.S. adult population with pre-diabetes. The target cohort will aim to include a large number of minorities (30-40%, including Black or African American, American Indian/Alaska Native, Asian, Native Hawaiian/Pacific Islander,

Hispanic) and women (50%). Participating clinical sites, where recruitment will take place, are selected to ensure adequate distribution of these characteristics in the cohort.

Potential Differences by Race and Ethnic Composition – In the preliminary studies, there was no difference among whites vs. non-whites in the association between 25OHD and incident diabetes in the DPP²⁵ or with vitamin D supplementation (CaDDM trial).²⁴ Nevertheless, given that non-whites have higher risk of t2DM and different vitamin D-calcium homeostasis, the D2d trial aims to recruit a large proportion, of *non-whites and analyses will test for heterogeneity of treatment effect by race and ethnicity*. *Race or ethnicity appear to be better determinants of 25OHD variability than objective measures of skin color*¹⁸⁵ suggesting that behavioral variables or physiological variables, other than biosynthesis, may be important in determining 25OHD concentration. Therefore, the D2d study has not incorporated objective measures of skin color in the study design, because these methods are labor-intensive and difficult to standardize among sites. Race and ethnicity data will be collected by participant self-report.

5. STUDY POPULATION

Specific participation (inclusion/exclusion) criteria are described below. A brief justification for each inclusion/exclusion criterion, if necessary, is shown in brackets [...]

5.1 Inclusion Criteria

1. Pre-diabetes (“at increased risk for diabetes”) defined by meeting 2-out-of-3 of the following glycemic criteria, established by the ADA in the 2010 clinical practice guidelines, at the baseline visit.²³²
 - a. FPG 100-125 mg/dL, inclusive
 - b. 2hPG 140-199 mg/dL, inclusive
 - c. HbA1c 5.7-6.4%, inclusive
2. Age ≥ 30 years. [Age is a major risk factor for type 2 diabetes; avoid “contamination” with type 1 Diabetes or Latent Autoimmune Diabetes of Adults, conditions that have a different pathophysiology; minimize loss to follow-up due to social mobility; facilitate recruitment and increase applicability of findings]
3. BMI ≥ 25 (23 kg/m² for Asians) and ≤ 40 kg/m². [Overweight/obesity is a major risk factor for type 2 diabetes; those with severe obesity require higher doses of vitamin D²³⁷]
4. Provision of signed and dated written informed consent prior to any study procedures.

5.2 Exclusion Criteria

Exclusion Criteria were selected to: (1) ensure participants’ safety; (2) avoid conditions that would affect the outcomes (i.e. minimize competing risk); (3) make recruitment targets realistic; (4) amplify generalizability of study results; (5) maximize participants’ adherence with study procedures.

1. Diabetes based on *either* of the following criteria:
 - a. History (past 1 year) of hypoglycemic pharmacotherapy (oral or injectable medication approved by the FDA for type 2 diabetes) used for any condition (e.g. pre-diabetes, diabetes, polycystic ovarian syndrome).
 - b. Meeting glycemic criteria for diabetes, as defined by the ADA guidelines (FPG ≥ 126 mg/dL, 2hPG ≥ 200 mg/dL or HbA1c $\geq 6.5\%$).
2. History (past 3 years) of hyperparathyroidism, nephrolithiasis or hypercalcemia. [Safety]
3. Any medical condition (past 3 years) that in the opinion of the site investigator may increase risk for nephrolithiasis or hypercalcemia during the trial (e.g. sarcoidosis). [Safety]
4. Visit to tanning booth within 12 weeks of the baseline visit and unwilling to stop visiting tanning booths for the duration of the study [interference with intervention]

Medications and Supplements

5. Use of supplements containing vitamin D at total doses higher than 1000 IU/day within 12 weeks of the baseline visit initiating the protocol and unwillingness to limit vitamin D supplementation dosage to no higher than 1000 IU/day for the duration of the study. [Safety]
6. Use of supplements containing calcium at total doses higher than 600 mg/day within 1 week of the baseline visit initiating the protocol and unwillingness to limit calcium supplementation dosage to no more than 600 mg/day for the duration of the study. [Safety]
7. Current use of medications or conditions (e.g. untreated celiac disease) that would interfere with absorption or metabolism of vitamin D.
8. Current use of medications approved by the FDA for weight management.
9. Use of thiazide diuretics at a total dose greater than 37.5 mg/day.
10. Use of anticonvulsant drug started within 6 months of screening. Stable regimen of anticonvulsants is allowed.

11. History of intolerance to vitamin D supplements. [Safety]

Other Medical History

12. Severe symptomatic cardiovascular disease based on history and physical examination (unstable angina, dyspnea on exertion, paroxysmal nocturnal dyspnea, arrhythmia, congestive heart failure NYHA class II or higher, claudication).
13. History (past 1 year) of myocardial infarction, percutaneous coronary intervention or coronary artery bypass graft. [Safety]
14. History (past 1 year) of cerebrovascular disease (stroke, transient ischemic attack). [Safety]
15. Any type of cancer (past 5 years) except for basal cell skin cancer. [Safety] Participants with prostate cancer (for men over age 55) or well-differentiated thyroid cancer that are not expected to require treatment (except for suppression with thyroid hormone) over the next 4 years are not excluded.
16. History (past 6 months) of treatment with oral (for > 7 days) or intravenous glucocorticoids or disease likely to require oral or intravenous glucocorticoid therapy during the study (inhaled glucocorticoids are *not* excluded). [Interference with outcome assessment]
17. History (past 1 year) of substance abuse or unstable psychiatric disorder that in the opinion of the site investigator would impede competence or adherence with study procedures or hinder completion of the study or increase risk. [Safety, adherence]
18. History of bariatric surgery (e.g. Roux-en-Y Gastric Bypass) or planned bariatric surgery in the next 3 years. [Interfere with vitamin D absorption]
19. A life-threatening event within 30 days of screening or currently planned major surgery.
20. Any other unstable active medical condition (including but not limited to liver disease, wasting illness, AIDS, tuberculosis, oxygen-dependent chronic obstructive pulmonary disease, organ transplant, Cushing's syndrome) that in the opinion of the site investigators would impede competence or adherence with study procedures or increase risk. [Safety, adherence, plasma 25OHD may decrease as an acute-phase response^{253,254}]
21. Uncontrolled hypertension (systolic blood pressure > 160 mm Hg or diastolic blood pressure > 100 mm Hg). [Safety]
22. Poor venous access. [Safety]

Laboratory Evaluation

23. Serum liver transaminase (ALT or AST) higher than 3 times the normal range for the clinical site's laboratory [safety]
24. Anemia (hematocrit < 32 for women, < 36 for men), transfusion (within 6 months of screening or chronic requirement), blood donation (within 3 months of screening) or other condition (hemolysis, hemoglobinopathy) rendering HbA1c results unreliable as indicator of chronic glycemia. [Interference with outcome assessment] Transfusion or blood donation does not exclude participant
25. Low platelet count (< 50,000). [Safety for blood draws]
26. Chronic kidney disease, defined as estimated glomerular filtration rate [GFR] < 50 mL/min, from creatinine measured at the clinical site's laboratory and GFR calculated centrally. [Vitamin D homeostasis changes as GFR declines. These changes start when GFR falls around 40-60 mL/min.^{255,256} The planning committee selected 50 mL/min as the exclusion cutoff to ensure that participants maintain GFR > 40 mL/min during the study] Please note: to prevent potential confusion, GFR units will be denoted as mL/min throughout the protocol and associated documents.
27. Hypercalcemia, defined as serum calcium concentration greater than the upper limit of normal, measured at the clinical site's laboratory. [Safety]
28. Hypercalciuria, defined as spot urine (morning void) calcium-creatinine ratio > 0.275.²⁵⁷ [Safety]

Other

- 29. Participation (within 30 days of screening) in another interventional research study. [Conflict, "contamination"]
- 30. Previous randomization in the D2d study. Participants who did not qualify after screening may be screened again if the prior reason for exclusion has been addressed (e.g. high blood pressure is treated).
- 31. Any other reason that in the opinion of the site investigator would impede adherence with study procedures or hinder completion of the study or increase risk. (e.g. inability to follow instructions or understand the informed consent, dementia, unable to remain in the program for the duration of the study, inability to comply with the study protocol for any reason). [Safety, adherence]

Women only

- 32. Pregnancy (past 1 year by report or positive pregnancy test at screening), intent to become pregnant in the next 4 years or unprotected intercourse. [Safety] History of gestational diabetes is *not* an exclusion criterion.
- 33. Currently breastfeeding. [Safety]
- 34. Use of oral contraceptives started within 3 months of baseline. Stable regimen of oral contraceptives or any other hormonal method of contraception (e.g. implantable) is allowed. [Safety, interference with intervention]

6. RECRUITMENT AND ENROLLMENT OF PARTICIPANTS

6.1 Recruitment overview

Potential participants will be recruited from the collaborating clinical sites after IRB approval of the protocol. The screening and informed consent process is staged in 2 parts, *Pre-screening* phase followed by a formal *Screening* visit, (Figure 4.1) to: (1) maximize the prospective participant's understanding of the study purpose and procedures required for an informed decision regarding participation; (2) to promote efficiency.

The pre-screening phase will be site-specific and may take place in one or two stages that may include an additional visit (i.e. over the phone or web-based pre-screening [pre-screening-stage 1], followed by a visit [pre-screening-stage 2]. Each site, based on their prior experience, will provide a detailed site-specific recruitment plan that includes a pre-screening recruitment strategy to identify individuals with high likelihood of pre-diabetes that will be invited in for the formal screening visit, which will be identical for all sites. The intent of the staged pre-screening phase is to allow collaborating sites flexibility in their approach of recruiting participants, while maintaining a standard study-specific set of inclusion/exclusion criteria. Publicity and recruitment efforts are the responsibility of the sites; however, the CC will assist with centrally prepared and disseminated publicity and recruitment procedures and tools (e.g. brochures, flyers, and posters). Active recruitment will take place year round at regular rates of enrollment to ensure equal exposure of all participants to UV-B.

6.2 Recruitment Progress

Recruitment of about 100-150 participants per site is expected to take place over a 2-year period. At each site, the research coordinator will work with the site PI and D2d Project Manager to develop a written site-specific recruitment plan that will be submitted to and reviewed by the Recruitment and Retention subcommittee prior to study initiation. Recruitment will be closely monitored and short-term recruitment goals will be established (based on total recruitment goals for each site) and reviewed monthly at each site and by the CC, quarterly by the Recruitment and Retention subcommittee and yearly by NIDDK, DSMB and local IRB. The overall recruitment goal is 4-8 enrolled participants per site per month. Based on review of recruitment progress, changes in the pre-screening strategy and site-specific recruitment plan may be required.

6.3 Informed Consent Process

At first contact with participants, prior to any study specific procedures, the informed consent process will be started. If the first contact is over the phone, a sample script will be read to the potential participant providing a brief overview of the study, informing him/her that they will be asked questions to determine if they are potentially eligible, and if they are potentially eligible they will be invited to the research site for a screening visit. The potential participant will then be asked if they would like to continue with the call. If the first contact is over the web, a web-based version of the script will be provided and the potential participant will be informed that they can discontinue the web based questionnaire at any time. At the initial visit, written informed consent will be obtained prior to any study procedures. A qualified member of the site research team (e.g. site PI, co-investigator, research coordinator, research assistant or clinical research nurse) will discuss with the potential participant the study's purpose, procedures, risks, potential benefits, and rights as a participant. Once all questions have been answered and concerns addressed, the potential participant will be asked to sign the written informed consent form. The informed consent process is ongoing and interactive. Participants will be given the opportunity to ask questions throughout their participation in the study. Participants will be told that they can cease participating in the study at any time for any reason. A written

“withdrawal of consent” will be requested for participants who elect to discontinue active participation from the study (i.e. go “off study”).

6.4 Pre-Screening

Clinical sites will employ a variety of sources including electronic databases (e.g. electronic medical records and research volunteer databases); community-based advertising (e.g. hospital newsletters, and specific local newspapers); targeted outpatient hospital clinics (e.g. primary care, cardiology); mailings to primary care physicians in the each metropolitan area; social media (e.g. craigslist), and study press releases to local news media to recruit potential participants. A separate public web page has been created for the D2d study that each site can refer to in their local advertisements. The web site will also provide national exposure and will provide interested participants with the contact information to the local sites. Because pre-diabetes is not a diagnosis with its own ICD code, the study will emphasize pre-screening based on presence of self-reported major risk factors (age, weight, family history etc.) and objective data (e.g. HbA1c) that are available through electronic medical records. The goals of the pre-screening phase are to: (1) identify potentially eligible participants; (2) initiate the informed consent process; (3) conduct a preliminary verification of eligibility criteria; (4) promote efficiency by pre-selecting candidates with high likelihood of eligibility after formal screening. The pre-screening strategy is site-specific and is based on what has worked well previously at the participating site. Each site will describe in detail their procedures for identifying participants likely to have pre-diabetes, based on meeting the major inclusion/exclusion criteria that will be invited for a formal screening visit. For example, a site may employ a diabetes-risk engine (e.g. ADA Diabetes Risk Score) to pre-screen volunteers over the phone, via the web or in-person.

6.5 Screening & Assessment of Eligibility

The goals of the formal screening visit are: (1) complete the informed consent process and obtain written informed consent; (2) initial assessment of eligibility. Volunteers will be seen at each site in the morning after an overnight fast for a screening visit lasting approximately 1.5 hours. At this visit, after written informed consent is obtained (unless it has been obtained already during a pre-screening optional visit), the following will be performed: medical history and physical examination, vital signs (height, weight, blood pressure and heart rate), and laboratory measurements to assess eligibility for the study (complete blood count, liver function tests [AST, ALT], serum calcium, serum creatinine and estimation of creatinine clearance, pregnancy test for women with reproductive potential, FPG and HbA1c). Laboratory analyses during the screening visit will be performed locally.

Volunteers will be invited to the baseline visit if they meet the following criteria at the screening visit: (see Figure 6.1):

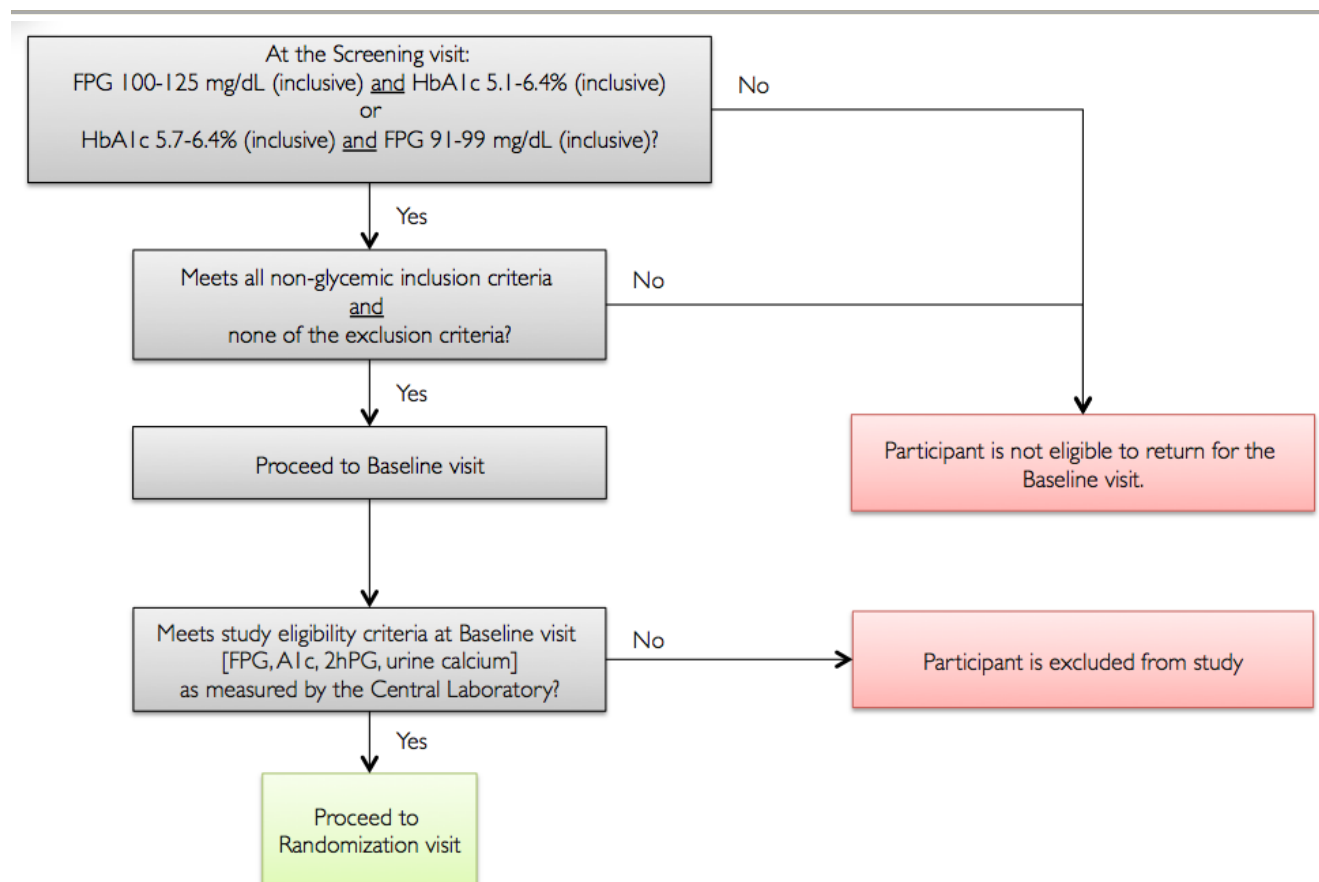

- a) FPG 100-125 mg/dL (inclusive) and HbA1c 5.1-6.4% (inclusive) or HbA1c 5.7-6.4% (inclusive) and FPG 91-99 mg/dL (inclusive)
- b) Meet all other non-glycemic inclusion criteria and meet none of the exclusion criteria

At the baseline visit, a 75-gram OGTT will be performed to obtain blood for FPG, 2hPG and HbA1c to confirm the glycemic eligibility criteria and to collect urine to confirm the calcium-creatinine ratio eligibility criterion. The Central Laboratory will conduct the analyses of tests obtained at the baseline visit. Volunteers who meet the non-glycemic eligibility criteria at the screening visit (measured locally) and the glycemic and urine criteria at the baseline visit (measured by the Central Laboratory) will be enrolled in the trial.

Multiple screenings will be allowed for participants who missed the inclusion/exclusion criteria by a small margin. For example, if a participant does not qualify due to high blood pressure, she may

return for screening after her hypertension is treated. It will be up to the site PI to decide when a participant may return for re-screening.

Figure 6.1: Flow diagram of assessment of eligibility at screening and baseline visits

6.6 Retention of Participants / Avoidance of Missing Data

Each site will build on its experience to maximize participant retention. In general, the following will be implemented: (1) Participants will be followed until study end, even if they discontinue randomized treatment, have initiated other interventions or unmasking has occurred. Participants will be educated on the importance of completing all assessments. (2) At every visit, participants will receive information and tips to promote retention and adherence to study procedures.^{258,259} (3) Participants who are lost to follow-up but have not gone formally “off study” will be termed “inactive” to reflect the possibility that they will resume adherence with study medication and will return for outcome measurements. (4) Sites will employ a variety of methods to promote retention by maximizing rapport with participants and their families as described in section 7.6.

In addition, as part of the Support and Education Program (described earlier), participants will be invited to attend group meetings, held twice yearly at each site, to discuss specific topics in nutrition, exercise and diabetes (e.g. healthy eating strategies for the holidays). These meetings will allow the opportunity to meet other participants and will serve as a way to enhance retention. Finally, at regular intervals, the CC will develop a D2d study newsletter and provide to the sites, which they can further customize by adding their logo and any other relevant site-specific information and send to participants by mail or e-mail. The newsletter will have a section on healthy nutrition and exercise and will also include specific tips to promote adherence.

6.7 Participant Study Stipend

Participants will be reimbursed for their time and effort during the study visits and for the cost of transportation and/or parking. The rates, timing and form of reimbursement will be determined by the expected time requirement and complexity of the study visit and may differ by site. A site-specific stipend schedule will be described in the informed consent form for each site.

7. STUDY INTERVENTION

7.1 Summary

Participants will be randomized to two equal groups and assigned to vitamin D₃ or matching placebo. Treatment assignment will be double masked.

7.2 Study Pills

7.2.1 Description of Vitamin D and Placebo Pills

Vitamin D or placebo will be dispensed as a single pill taken daily. The vitamin D pill will be a white soft-gel containing 4,000 IU of cholecalciferol [D₃] and additional (inert) ingredients. The placebo pill will be a soft-gel identical looking in size, shape, texture, color, odor and taste with the same inert ingredients as the active pill, but without vitamin D. The bottles that will hold the active or placebo pills for distribution to the participants will also be identical. Based on stability studies, the manufacturer has established the expiration period for both vitamin D and placebo pills to be at least 24 months at the required storage conditions. The actual contents of both active and placebo pills will be confirmed at the beginning of each manufacturing lot, as described below.

7.2.2 Manufacturing, Formulation, Packaging and Labeling

Tishcon Corp. will prepare the vitamin D₃ and matching placebo soft-gel pills intended for oral administration according to the United States Pharmacopeia standards and Good Manufacturing Practices. The manufacturer will ship study pills to the Drug Distribution Center in bulk where they will be packaged into bottles with enough pills (vitamin D₃ or placebo) for a 6-month period plus enough additional pills in case participants need to postpone their follow-up visit for up to 8 weeks. The Drug Distribution Center will code each bottle with a unique serial number that links to its contents (vitamin D or placebo). This number will be linked to the randomization scheme and drug dispensation at baseline and during each 6-month visit. The expiration date and any other information required by local and federal regulations will be printed on the bottle.. The bottles and labels for the vitamin D and placebo pills will look identical except for the unique serial number.

7.2.3 Quality Control

The manufacturer (Tishcon Corporation) performs quality control analyses on each lot that is shipped from the manufacturing plant. A Certificate of Analysis is generated by Tishcon Corp. and supplied to the Drug Distribution Center and the CC documenting quality control, including assaying for the amount of the active ingredient (vitamin D₃) to ensure that variation from the labeled claim is within United States Pharmacopeia specifications. In addition, when the Drug Distribution Center receives the study pills, it conducts an independent quality control that includes potency analysis of the contents prior to release of the product to the sites. If the results of the initial testing by the independent source (Drug Distribution Center) are outside of the desired range, Tishcon Corp. will manufacture a new lot and the above process will be repeated. In addition, the Drug Distribution Center will perform long-term stability testing to confirm that the potency of vitamin D has remained stable during the 24-month shelf life.

7.2.4 Accountability Procedures for the Investigational Product(s)

Bottles with study pills will be stored at the Drug Distribution Center until shipment to sites. Study pills will be shipped from the Drug Distribution Center to each site's research pharmacy where pills will be stored under Good Clinical Practices. If a site does not have a research pharmacy available, an

alternative storage and distribution plan must be provided to and approved by the CC and the Drug Distribution Center. The Drug Distribution Center will work closely with the CC, the study pill manufacturer and all sites, using a web-based real-time inventory and randomization system (Interactive Web Response System), to monitor supply chain and manage inventory and to ensure that an adequate supply of bottles with vitamin D and placebo soft-gels are present at each site at all times. Upon receipt of the study pills, the site pharmacist or designee will review the shipping document and confirm receipt of the study pills on the Interactive Web Response System. After the initial shipment, subsequent shipments to sites will be determined based on recruitment rate and site inventory that will be actively monitored in real time via the Interactive Web Response System.

At randomization and every six months, the site research pharmacy or designee, using the Interactive Web Response System, will distribute study pills to the research staff for distribution to participants according to the randomization code.

Study staff will review study pills returned by participants at each visit. Pill counts will be completed by a member of the research staff and documented. The returned unused pills will then be destroyed following local guidelines and documented.

7.3 Randomization and Masking

7.3.1 Randomization Process and Sequence Generation

Randomization will be in a stratified and blocked fashion in a 1:1 ratio. Stratification factors will be by site, BMI (<30 or ≥ 30 kg/m²) and race (White or non-White [e.g. American Indian, Asian, Pacific Islander, Black]). Using stratified randomization helps balance the number of participants in each group for BMI and race, which are major determinants of vitamin D status and diabetes risk. The use of permuted blocks within each stratum will guarantee the balance between the two treatment arms during the course of randomization. The randomization will be administered by the Drug Distribution Center via the Interactive Web Response System.

Upon the participant's arrival at the randomization visit, the site research coordinator (or his/her approved designee) will log into the Interactive Web Response System and will enter the required stratification information (site, BMI and race). The system will generate the stratified randomization and assign a pill bottle that matches the assigned cohort (vitamin D or placebo). The research coordinator will then notify the site research pharmacist of the pill bottle number. The site pharmacist or designee will dispense a six-month supply of masked study pills to the research coordinator or nursing staff for distribution to participants.

7.3.2 Allocation Concealment (Masking)

Assignment will be double-masked. Participants will be masked as to the composition of their pills. All study personnel, including site investigators, research coordinators, nurses, pharmacists and laboratory staff, will also be masked. Results of laboratory tests will not be provided to participants with the exception of the results obtained at the screening visit. Certain variables (medical history and physical examination, vital signs, waist circumference) will be reported to participants, as it is not feasible to keep these data masked from the participants.

The randomization code will be masked until data files have been cleaned and locked and data analyses are completed.

7.3.3 Breaking of Randomization Code (unmasking)

At no time will the code of the treatment assignment be broken without the expressed knowledge and consent of the site PI and the CC. Unmasking will only occur if there is a serious adverse event (SAE) or any other adverse event (AE) that is “severe” and “probably related” or “definitely related” to the study pill, *and* the site PI (and site study physician, if site PI and physician are not the same person) determines it is necessary for the care of the participant to be unmasked. It is expected that almost all AE and SAEs will be handled without unmasking. If it is determined that the masking needs to be broken, then study pills will be discontinued and the assignment will be disclosed only to research personnel that need to know (e.g. site PI, site study physician and/or research coordinator). Participants who discontinue study pills will not go “off study” and will remain in the study and return for all remaining scheduled follow-up visits and procedures, consistent with the intention-to-treat principle. It is expected that unmasking will be exceedingly rare as it will be restricted to situations in which knowing the assignment will change the course of care of the participant. When unmasking occurs, the site PI will review and report to the CC and IRB the circumstances that led to it.

7.4 Administration of Study Pills

Participants will be asked to take the study pills daily in the morning, preferably with breakfast, until the end of the trial and to bring the pill bottles with them to all scheduled visits for adherence assessment. During the scheduled 6-month visits, participants will return the study pill bottles and receive new bottles with a supply of pills for the next 6 months (plus enough additional pills in case participants need to postpone their follow-up visit for up to 8 weeks).

Every time participants receive a new bottle of pills, they will receive written instructions on proper administration of the study pills and the need to report any changes in their health or medications to the research staff. The research staff will also review instructions verbally. Participants will also receive information and tips to promote adherence with study pills.

7.5 Modification of Study Intervention for a Participant

A participant will stop the study pill if the primary outcome (diabetes) is reached but will continue to return for scheduled follow-up visits until study end to assess non-diabetes outcomes. If a participant is unable to tolerate the study pills due to safety concerns (i.e. symptom, sign or laboratory abnormality) or for any other reason, study pills will be discontinued. Study pills will also be stopped at participant’s request. Study participants may temporarily discontinue study pills for an adverse event (that is unrelated to study pills) or for other reasons. Participants who permanently discontinue study pills will remain in the study and return for all remaining scheduled follow-up visits until study end, consistent with the intention-to-treat principle. The importance of remaining in the study, even if they stop taking the pills, will be emphasized to participants during the informed consent process.

7.6 Adherence with Study Procedures and Study Pills

Participants’ adherence to study procedures is critical to the successful conduct of the D2d study, especially on its impact on power; therefore, the study will aim to maximize adherence, by taking the following steps: (1) Prevent/minimize potential adherence problems before participant enrollment, as follows: the study design has kept the intervention (i.e. single daily dose study pill regimen) and follow-up procedures uncomplicated; the informed consent process will emphasize the importance of adherence; exclusion criteria include potential those with higher probability of non-adherence. (2) Maintain/enhance adherence during the trial, as follows: participants will be seen three times during the first 6 months (at baseline, 3-month and 6-months) and every 6 months for the remainder of the study; at the midpoint of each 6-month interval, participants will receive a telephone call to encourage

adherence, assess for adverse events or changes to medical history and concomitant medication use and be reminded of their upcoming visit (alternatively, participants may also be contacted via email, or text based on their preference); study staff will provide participants with a personalized study calendar with visit dates; at every visit, participants will also receive information and tips to promote retention and adherence to study procedures; each site PI, co-investigators, research coordinator and staff will be available to answer participants' questions and will maintain a flexible schedule to meet the participants' needs; sites will also employ a variety of site-specific methods to promote retention by maximizing rapport with participants and their families (e.g. holiday and/or birthday cards). (3) Monitor adherence during the study based on pill counts (at every 6-month visit). Individual adherence to study medication will be defined as a pill intake over 80% based on pill counts. If a participant does not meet the adherence minimum target of 80% at any visit, s/he will be reminded of the importance of adherence to the study's objectives, the administration instructions will be reinforced and the site research staff will work with the participant to identify causes that contribute to suboptimal adherence and develop approaches to overcome barriers to adherence. Adherence during the study will also be monitored by measurement of the physiological response biomarker to vitamin D supplementation (plasma 25OHD concentration) at yearly intervals. A pre-specified absolute level of increase in 25OHD concentration cannot be used for adherence for each participant given the individual variation in response to supplementation, although it is expected that adherent participants will have a rise in 25OHD concentration from baseline. The 25OHD concentration will not be available in real-time as measurements will be conducted at the end of the study. Planned subgroup analyses will test for effect modification by adherence based on (1) pills counts and (2) achieved plasma 25OHD concentration (see Section 11).

8. PROCEDURES AND OUTCOME MEASURES

8.1 Study Visits and Phone Calls

The baseline visit (BAS) should occur after the results of screening lab analyses have been reviewed and preliminary eligibility determined, within 4 weeks of the screening visit. The site investigator will review the results of the baseline visit laboratory measures and determine if the participant meets the study eligibility criteria. If eligibility is confirmed the participant will return for the randomization visit, within 3 weeks of the baseline visit. Participants will be seen until study end. Visits will occur at 3 months (M03), 6 months (M06), and every 6 months thereafter (e.g. M12, M18) until study end. Follow-up visits should occur within ± 2 weeks of the scheduled date. However, follow-up visits may be postponed for up to 8 weeks if a temporary concomitant condition exists that would affect glucose tolerance (e.g. infection) or its assessment (e.g. blood transfusion or blood donation) or for any other administrative or social reason. The reason for the postponement of the visit will be documented in the electronic data capture system.

During each follow-up visit, the research coordinator will assess study pill adherence, question the participant regarding the occurrence of adverse events or changes to medical history and concomitant medication use.

Phone contact is scheduled at the midpoint of each 6-month follow-up visit after the 6-month visit (e.g. M09, M15). Participants will be contacted by the research coordinator to encourage adherence, assess for adverse events or changes to medical history and concomitant medication use and be reminded of their upcoming visit (alternatively, participants may also be contacted via email, text or twitter based on their preference).

Unscheduled visits may occur between scheduled visits for the following reasons:

- Evaluation of adverse events.
- Confirmatory testing for assessment of the primary outcome, as described in section 9.
- Primary outcome achieved or administrative censoring required, as described in section 9.

In addition, participants will receive reminder communication (phone call, letter, email or text) one week prior to each scheduled visit.

8.2 Laboratory Procedures and Outcomes

Laboratory samples will be collected during scheduled visits and also in-between visits, as needed to evaluate symptoms consistent with diabetes or adverse events. All laboratory tests and procedures will be done in the morning and participants will be instructed to fast overnight prior to the visit for at least 8 hours. Screening and safety assessments (with the exception of urine calcium-creatinine ratio) will be analyzed at each site's clinical laboratory. Laboratory samples for assessment of outcomes will be collected and processed at each site and then sent to the Central Laboratory for storage and analyses. Site clinical laboratories and the Central Laboratory will process samples and conduct all measurements in a masked fashion.

8.2.1 Screening Laboratory Tests

The following laboratory tests will be drawn and analyzed *at each site's clinical laboratory during the screening visit*. The results of the following tests will be used to determine participant's initial eligibility for the study:

- Complete blood count (CBC: white blood cell count without differential, hemoglobin/hematocrit, platelet count)
- Liver transaminases (AST, ALT)
- Serum calcium
- Serum creatinine and estimated creatinine clearance (GFR, calculated centrally)
- Pregnancy test for women of reproductive potential. Point-of-care urine testing will be done followed by confirmatory blood testing, if point-of-care urine test is positive. If point-of-care urine testing is not an option, a urine or serum test will be done at the site's laboratory.
- FPG *
- HbA1c *

Tests with a * next to them will be repeated during the baseline visit. Prior to study initiation, each site will provide the CC with the site's clinical laboratory's reference ranges for the above tests.

The following laboratory tests will be drawn and analyzed *at the Central Laboratory during the baseline visit*.

- Urine calcium-creatinine ratio (early morning spot urine specimen)
- FPG
- HbA1c
- 2hPG (OGTT)

8.2.2 Safety Laboratory Tests During the Study

To monitor safety, the following laboratory tests will be drawn and analyzed at each *site's clinical laboratory* at M03, M12, at yearly visits thereafter, and as needed to evaluate symptoms and/or physical signs.

- Serum calcium
- Serum creatinine and estimated creatinine clearance (GFR, calculated centrally)

To monitor safety, the following laboratory test will be drawn at the sites but analyzed at the Central Laboratory at BAS, M03, M12, at yearly visits thereafter, and as needed. The Central Laboratory will analyze the urine calcium-to-creatinine (instead of the site's clinical laboratory) because: (1) this variable also serves as a safety outcome of interest and would be important to standardize its measurements; (2) the result does not need to be communicated back to the participant urgently.

Urine calcium-creatinine ratio

NOTE: Analyses will be done according to a schedule determined by the Central Laboratory

To monitor safety, the following laboratory test will be drawn and analyzed at each *site's clinical laboratory*.

Pregnancy test for women of reproductive potential who report missing two consecutive menstrual periods (based on their typical cycle).

8.2.3 Outcome Laboratory Tests

At scheduled visits, as shown below, blood and urine samples will be collected and processed (prepared for freezing and shipping) at each site and then sent to the Central Laboratory for immediate analyses of the outcome measures and storage for subsequent planned analyses and future ancillary analyses.

At baseline (BAS) and annually, the following will be collected and analyzed upon receipt of the specimens by the Central Laboratory and results will be communicated back to the clinical site.

- FPG, HbA1c, 2hPG (from the OGTT)

These glycemic tests will be used to confirm participant's eligibility for the study. If participant meets the study criteria for diabetes at baseline, the participant will not be randomized and their participation will end. The participant will be referred to their primary care provider.

Results of the following tests are not required in real-time and analyses will be done according to a schedule determined by the Central Laboratory:

- Glucose (from the OGTT at 30 minutes)
- Insulin (fasting, 30 minutes and 120 minutes from the OGTT)
- 25OHD

The following will be stored for future studies:

- Blood (plasma and serum) and urine
- Whole blood for DNA (collected at BAS visit only)

At each of the in-between 6-month visits (e.g. M06, M18), the following will be collected and analyzed upon receipt of the specimens by the Central Laboratory and results will be communicated back to the clinical site:

- FPG, HbA1c

The following will be collected at the M06 visit only and stored for future studies:

- Blood (plasma and serum)

At the M03 visit, the following will be collected and analyzed upon receipt of the specimens by the Central Laboratory:

- Urine calcium-creatinine ratio (see section 8.2.2)

Additional testing. In addition to the above scheduled laboratory tests, if any one of the following laboratory measures (FPG, HbA1c, 2hPG) meets the ADA criteria for diabetes, a confirmatory visit will be completed to repeat the measures as described in section 9. The Central Laboratory will notify the clinical site of the need for repeat confirmatory testing via the electronic web-based data capture system. A diagnosis of diabetes will be made when any two sequential glycemic measures are positive for diabetes as described in section 9.1.

After participants reach the diagnosis of diabetes, study pills will be discontinued without unmasking and participants will continue in the study and complete all subsequent planned visits. After the participant has reached the primary outcome (diagnosis of diabetes), tests for safety (serum calcium, serum creatinine and urine calcium-creatinine ratio), OGTT and serum for insulin will not be drawn. However, the following blood and urine samples will continue to be collected, per the study schedule:

- FPG
- HbA1c
- 25OHD
- Blood and urine for storage

8.3 Vital Signs

Vital signs composed of height, weight, blood pressure and heart rate will be assessed at screening, baseline and at all follow-up and unscheduled visits. Waist circumference will be measured at baseline only. Results of these measurements will be reported to participants, as it is not feasible to keep these data masked from participants.

8.4 Other Measures / Assessments

- Food Frequency Questionnaire

A validated self-administered semi-quantitative food frequency questionnaire will be used to estimate self-reported vitamin D and calcium intake and other nutrients of interest at baseline, month 12 and month 36 in participants free of diabetes.

- Physical Activity Questionnaire

Physical Activity (kcal/d) will be measured by the 7-day International Physical Activity Questionnaire at baseline, 6-month visit and annually.²⁶⁰

8.5 Withdrawal from the study (going “off study”)

The study will distinguish between “non-retention” (being off study) and “non-adherence” (being off study medication). Participants can withdraw from the study, i.e. go “off study,” for withdrawal of consent, which is defined as no longer wishing to participate in all aspects of the trial. The local investigator may withdraw participants for a safety reason. Proper use of the term “withdrawal of consent” will be monitored during the study.

Unless participants go permanently “off study”, they will be asked to return for all scheduled follow-up evaluations to collect outcome and safety data. Participants will be educated during the consent process and will be reminded at every visit on the importance of completing planned assessments. Participants, for safety reasons, personal choice or any other reason, may need to go “off study treatment;” however, they will continue with outcomes assessment as planned. Participants who are lost to follow-up but have not gone formally “off study” (i.e. have not provided a verbal *withdrawal of consent*) will be termed “inactive” to reflect the possibility that they will resume adherence with study medication and will return for outcomes measurements. Both “inactive” and “off study” participants are included in the estimated attrition rate that went into the sample size calculations (please see section 11.1).

9. ASCERTAINMENT OF OUTCOMES & POTENTIAL CONFOUNDERS

All interactions with study participants and all outcome measurements will be performed by study staff that is masked to study group assignment.

9.1 Primary Endpoint (Outcome)

The primary outcome will be *time to progression from pre-diabetes to incident (new-onset) diabetes, defined by laboratory criteria*, as follows:

Laboratory diagnosis of diabetes, based on the following ADA glycemic criteria²⁶¹ measured at study visits: FPG $\geq$ 126 mg/dL, 2hPG $\geq$ 200 mg/dL and/or HbA1c $\geq$ 6.5% (Figure 9.1.1 and 9.1.2).

All three glycemic measures will be assessed at scheduled yearly visits (M12, M24, M36 and M48) by conducting a 75-gram OGTT (Figure 9.1.1). If all three glycemic measures are negative for diabetes, then the participant does not have diabetes and will continue on the assigned treatment. If two or all three of the glycemic measures are positive for diabetes, the participant will be considered to have reached the diabetes outcome and no confirmatory testing is required. If only FPG or HbA1c is positive for diabetes, then a confirmatory visit to repeat the *same glycemic test that was positive* will be completed within 8 weeks. If the repeat measure is also positive for diabetes, then the participant will be considered to have reached the diabetes outcome. For example, HbA1c = 6.5% and FPG = 119 mg/dL at the scheduled annual follow-up visit and HbA1c = 6.6% at the confirmatory visit. If only the 2hPG is positive for diabetes, then a confirmatory visit (with an OGTT) to repeat all three glycemic measures will be completed within 8 weeks. If the repeat 2hPG is positive for diabetes, then the participant will be considered to have reached the diabetes outcome. If the repeat 2hPG is negative for diabetes but *both* repeat HbA1c and FPG are positive for diabetes, then the participant will be considered to have reached the diabetes outcome. Otherwise, the participant does not have diabetes and will continue on the assigned treatment.

Fasting plasma glucose and HbA1c will be assessed at scheduled semi-annual visits (M06, M18, M30, M42; Figure 9.1.2). If both glycemic measures are negative for diabetes, then the participant does not have diabetes and will continue on the assigned treatment. If both glycemic measures are positive for diabetes, the participant will be considered to have reached the diabetes outcome and no confirmatory testing is required. If only one of two glycemic measures (FPG or HbA1c) is positive for diabetes, then a confirmatory visit to repeat the *same glycemic test that was positive* will be completed within 8 weeks. If the repeat measure is also positive for diabetes, then the participant will be considered to have reached the diabetes outcome. For example, HbA1c = 6.3% and FPG = 127 mg/dL at the scheduled semi-annual follow-up visit and FPG = 129 mg/dL at the confirmatory visit.

At any time when symptoms consistent with hyperglycemia are reported, FPG and HbA1c will be measured, outside of a scheduled study visit. The algorithm for the semi-annual visit, described above, will be followed.

Blood for plasma glucose (FPG, 2hPG) and HbA1c will be drawn locally and shipped to the Central Laboratory for measurements. Results will be available to the site typically within 5 business days from day of shipment. The date of onset of diabetes is defined as the date of the first diagnostic glycemic value. When diabetes is diagnosed, study pills will be discontinued without unmasking and participants will continue in the study and complete all subsequent planned visits.

Tests for glycemia will be performed without interrupting the assigned treatment. Testing at one of the scheduled follow-up visits or confirmatory visits will be postponed for up to 8 weeks if a temporary concomitant condition exists that would affect glucose tolerance (e.g. active infection, hospitalization

which may also require temporary use of a diabetes medication), its assessment (e.g. blood transfusion or blood donation) or for any other administrative or social reason.

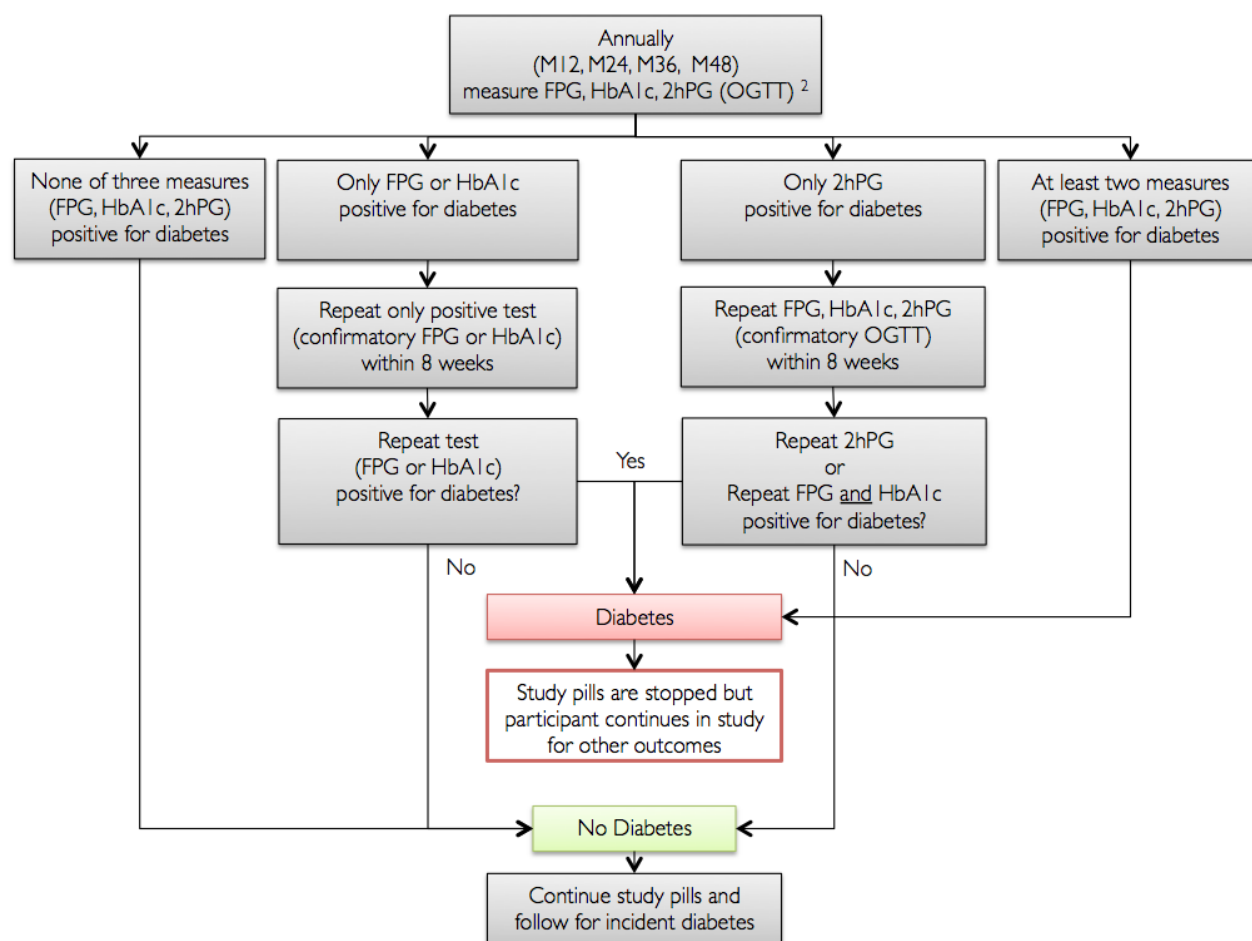

Physician-diagnosis of diabetes or use of diabetes-specific pharmacotherapy between scheduled visits self-reported by participants will be validated by laboratory testing as part of the study or by review of medical records by the Safety and Outcomes subcommittee (Figure 9.2). Participants will be advised to contact their site, as soon as possible after their health care provider makes the diagnosis of diabetes or if the health care provider plans to initiate diabetes-specific pharmacotherapy, so that participants return to the clinic for a visit outside the schedule to test for diabetes *before* they start any diabetes-specific medication. Diabetes-specific pharmacotherapy is defined as any FDA-approved medication for diabetes, including for uses not specific to diabetes (e.g. metformin for polycystic ovarian syndrome). At the study visit, participants will be asked questions related to their non-study visit with their health care provider and laboratory testing for diabetes will be conducted for FPG and HbA1c.

The algorithm for the semi-annual visit will be followed (Figure 9.2). If testing does not confirm the diagnosis, the participant will not be counted as an incident case of diabetes and will continue in the study on the assigned treatment. The site investigator will communicate the glycemic results (FPG/HbA1c) to the participant's health care provider for further management and to reinforce the principles of the study. If diabetes-specific pharmacotherapy is started despite the study-specific algorithm not confirming diabetes, participant will be considered as not having reached the outcome. Study pills will be discontinued without unmasking and participants will continue in the study and complete all subsequent planned measurements and visits. If diabetes-specific pharmacotherapy is not initiated based on study-specific laboratory glycemic results, participant will continue on study pills and be followed in the study.

If a participant has already started a diabetes-specific medication between study contacts, then no testing will be performed, study pills will be discontinued without unmasking and participants will continue in the study to complete all subsequent planned measurements and visits. Study staff will request medical records from the health care provider, with special emphasis on obtaining the most recent laboratory values for FPG, HbA1c or 2hPG before the diabetes-specific medication was started. Medical records will be centrally reviewed and the diagnosis of diabetes adjudicated by the Clinical Outcomes Committee to determine whether the outside laboratory results meet glycemic criteria for diabetes. Because HbA1c and glucose (FPG, 2hPG) are standardized tests across laboratories, this method is sufficiently robust to make the diagnosis of diabetes. The algorithms shown in Figure 9.1.1 and 9.2.2 will be followed as closely as possible during the adjudication process. If laboratory data from the health care provider cannot be obtained to adjudicate the diagnosis of diabetes, then the participant will be considered as not having reached the diabetes outcome. If there are several cases where data cannot be obtained and the diagnosis of diabetes cannot be adjudicated, the participant will most likely have clinical diabetes; therefore, sensitivity analysis will be conducted that includes events where diabetes was diagnosed by a health care provider but the event could not be adjudicated. Based on other diabetes prevention trials, it is expected that less than 5% of diabetes outcomes will be made exclusively based on out-of-study test results.¹²

When the participant meets a laboratory criterion for diabetes, the Central Laboratory will notify the collaborating site of the results and the need for repeat confirmatory testing via the electronic web-based data capture system. After the primary outcome has been reached, participants will stop the study pills and will be referred to their physician for further care in relation to diabetes. Participants will continue to return for scheduled visits until the end of the study for assessment of other outcomes. At the annual visits the HbA1c and FPG will be collected but the 75-gram OGTT for 2hPG will not be collected.

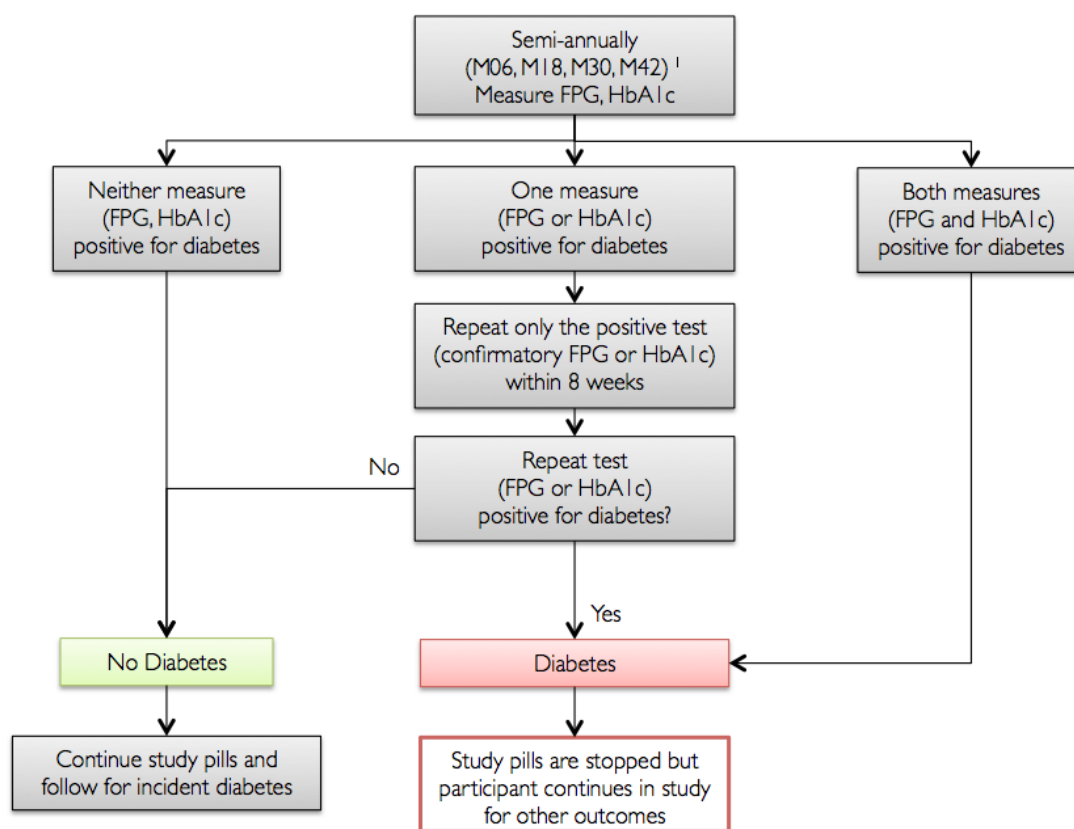

Figure 9.1.1. Flow diagram of laboratory diagnosis of diabetes at the annual visit

¹ FPG and HbA1c will also be measured in between scheduled visits at any time when symptoms consistent with hyperglycemia are reported.

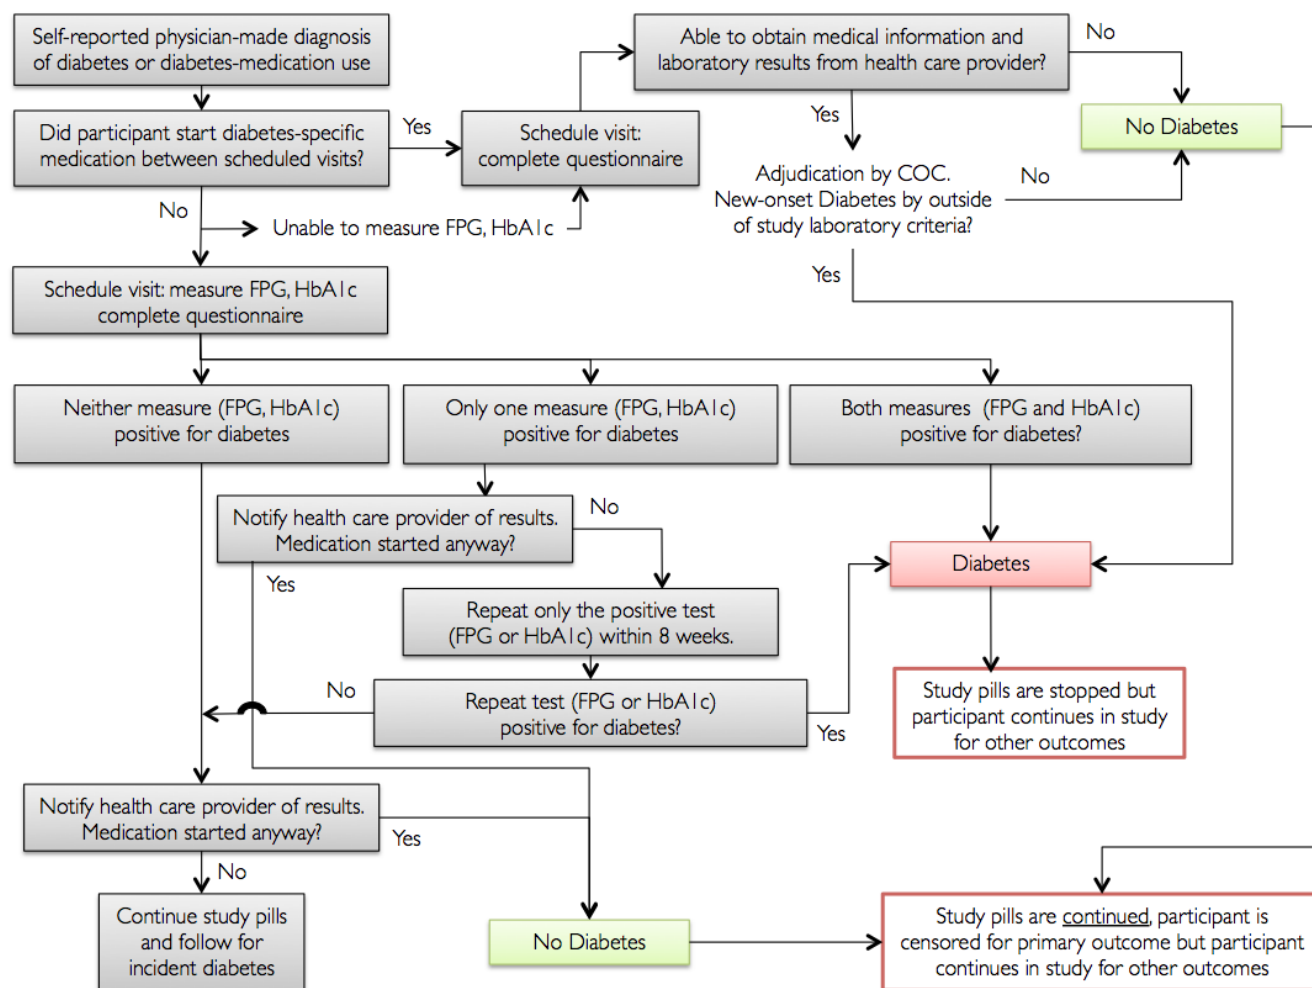

² During the annual OGTT, the following will also be drawn: insulin at 0, 30 and 120 minutes and glucose at 30 minutes

Figure 9.1.2. Flow diagram of laboratory diagnosis of diabetes at the semi-annual visits

¹FPG and HbA1c will also be measured in between scheduled visits at any time when symptoms consistent with hyperglycemia are reported.

Figure 9.2. Flow diagram for evaluating self-reported physician-diagnosis of diabetes or initiation of diabetes-specific pharmacotherapy between scheduled visits.

9.2 Secondary Endpoints (Outcomes) & Subgroup Analyses

The secondary outcomes were selected based on their importance to the underlying hypothesis of a potential link between vitamin D and type 2 diabetes (e.g. identify mechanisms that explain the effect of vitamin D supplementation on the primary outcome). Additional secondary outcomes that are not directly relevant to type 2 diabetes may be included, depending on budget and burden consideration, to increase our understanding of vitamin D physiology and its relevance to other outcomes, thereby maximizing the yield of the study. Secondary outcomes will be assessed in the entire cohort or in subsets of the study population, depending on statistical power needs, feasibility and availability of funding.

- Variability of response to vitamin D supplementation in subgroups defined by baseline characteristics: (1) race and ethnicity (as a proxy for skin pigmentation);¹⁸⁵ (2) BMI; (3) waist circumference;^{186,187} (4) age; (5) geographic location (proxy for sun exposure); (6) 25OHD concentration.
- Effect of vitamin D supplementation on HbA1c, FPG and 2hPG as continuous variables.

- Effect of vitamin D supplementation on insulin resistance and beta cell secretion (indices derived from the OGTT).
- Effect of vitamin D supplementation on plasma 25OHD concentration and determine phenotypic, including seasonal and geographic, characteristics associated with variability on achieved plasma 25OHD concentration.
- Safety and tolerability of vitamin D supplementation.

9.3 Potential Confounders or Effect Modifiers

Measurements to ascertain other exposures or variables that will serve as potential confounders or effect modifiers will be performed by staff masked to study group assignment.

Vitamin D status. Plasma 25OHD concentration will be measured as a proxy for vitamin D status at baseline and during the intervention to assess the efficacy of supplementation in the active arm and to compare between the two arms. *Self-reported vitamin D intake* will be estimated from a validated self-administered semi-quantitative food frequency questionnaire.^{18,233-236}

Calcium status. There are no widely accepted measures of adequate calcium status. Self-reported calcium intake will be used as proxy of calcium adequacy at baseline and during the intervention. *Self-reported Calcium Intake* will be estimated from a validated self-administered semi-quantitative food frequency questionnaire.^{18,233-236}

Other Potential Confounders or Effect Modifiers. In addition to vital signs (height, weight [BMI calculation], blood pressure and heart rate), waist circumference will be measured at baseline. *Physical Activity* (kcal/d) will be measured by the 7-day Modifiable Activity Questionnaire at baseline and at the annual visits.²⁶²

9.4 Concomitant Medications / Treatments

Information on all concomitant medications participants take, including prescription medicines, vitamins and dietary supplements (prescribed or over-the-counter), will be collected in regards to start/stop date, dose, frequency and indication. Participants will be instructed to follow the IOM recommendations for vitamin D and calcium intake. During the study, exogenous vitamin D supplementation cannot exceed 1000 IU/day, and calcium supplementation cannot exceed 600 mg/day, unless specifically prescribed by a physician.

9.5 Stored Specimens

Samples of plasma, serum and urine will be stored in small aliquots for future ancillary studies that are relevant to vitamin D or diabetes. At baseline, the study will collect whole blood for future DNA extraction, which will be done as part of a genetic ancillary study.

10. DATA AND SAFETY MONITORING

10.1 Risk-benefit analysis

The potential risks (probability and magnitude) to participants from the study intervention or procedures described in the research proposal are small and reasonable in relation to the anticipated benefits that may be reasonably expected to result from this study.

Please refer to the D2d study Data Safety Monitoring Plan for additional details.

10.1.2 Potential risks related to this study

The potential risks that may be seen in this study are described below.

“Expected” AE related to the *intervention, vitamin D supplementation* (uncommon).

- Hypercalcemia
- Hyperphosphatemia
- Nephrolithiasis
- Hypercalciuria
- Nephrotoxicity
- Anemia
- Polyuria
- Nausea
- Vomiting
- Poor appetite
- Weakness
- Fatigue
- Insomnia
- Headache
- Metallic taste

“Expected” AE related to *the underlying condition, pre-diabetes* (uncommon)

- Hypoglycemia
- Symptomatic hyperglycemia
- Cardiovascular events
- Infection
- Cancer

“Expected” AE related to *study procedures for outcome assessment (testing)*

Related to blood draws

- Minor discomfort from introducing the needle/catheter under the skin or skin bruise (common)
- A skin infection from the needle/catheter (rare)
- Mild anemia from repeated blood draws (rare)

Related to the OGTT

- Risks associated with insertion of needle/catheter and mild anemia as described above
- Phlebitis (rare)

- Symptoms or signs of hypoglycemia following the oral glucose load (uncommon)

Other risks related to overall trial participation

- Social-psychological risk due to inadvertent disclosure of confidential medical information (rare)

10.1.3 Protection Against Risk

Study staff at all sites will be trained and certified by IRB in the ethical conduct of human research.

Before the start of the study, to minimize the occurrence of “expected” AE and overall risk, the following measures will be taken:

- Participants who may be predisposed to AE as a result of the study intervention or procedures will be excluded (e.g. those with poor venous access will be excluded to prevent discomfort or skin infections).
- Renal stones are an unusual but not a rare complication of vitamin D supplementation, especially when combined with calcium. In this proposal, total calcium intake from supplements will be limited to 600 mg per day and participants will be randomized to 4000 IU of vitamin D daily or placebo. Although the 4000 IU per day dose is the tolerable upper limit (UL) for safety as determined by the Institute of Medicine (IOM), there is some risk that kidney stones could occur in the active treatment group at a higher rate than the control group. Hence, to minimize risk of nephrolithiasis, volunteers with high serum calcium at baseline, hyperparathyroidism, history of nephrolithiasis or other medical condition (e.g. sarcoidosis) that may increase risk for nephrolithiasis or hypercalcemia, will be excluded, as described in exclusion criteria. The study will monitor urine calcium excretion as a safety measure, as described in section 4.2.
- Women of reproductive potential will be instructed to use an effective method of birth control of their choice during the trial. Pregnancy testing will be conducted at the screening visit and as needed during the study.
- As part of the informed consent process, “expected” AE will be described to the participants and they will be instructed to report any changes in their health, complaints or problems during and between regular visits, whether they think the problem may be related to the study or not.
- As part of their informed consent process, participants will be instructed to contact the site PI (or his designee), site research coordinator, or research assistant at any time for any questions related to the study.
- Rules for discontinuation of study medications due to safety concerns are defined (please see section 7.5).
- The site PI will review the protocol and Manual of Procedures with study personnel (co-investigators, site research coordinator, nurses, etc.) and ensure that all personnel understand their responsibilities. All study personnel will be instructed to monitor for AE and be familiar with the reporting requirements for the different types of AE.

During the study, to minimize the occurrence of “expected” AE and overall risk, the following measures will be taken:

Intervention

- Serum calcium and creatinine (GFR), and urine calcium will be monitored at regular intervals.
- At each contact (phone or visit), participants will be questioned in regards to changes in their health or medications (prescription or non-prescription, including supplements).

Outcome Measures

- For all blood draws/catheter insertion, research staff will follow the usual sterile techniques and only experienced personnel will perform the procedure to minimize discomfort, bruising and risk of infection or bruising.
- To minimize the risk of anemia from repeated blood draws, the smallest amount of blood required for each testing procedure will be drawn.

Trial Participation

- A site study physician (or his designee) will be available at all times to evaluate and provide the necessary medical intervention in the event of an adverse event, or make a referral for the appropriate care.
- Risk to patient confidentiality is minimal because all study records are confidential within the study staff environment. Although the consent form will specify what protected health information will be collected and with whom it will be shared, an authorization form in addition to the consent form will be signed by participants from institutions that require a separate document in accordance with their interpretation of the Health Insurance Portability and Accountability Act (HIPAA) guidelines. Safety precautions and encryption of data will ensure that electronic systems do not pose a risk to participant confidentiality. Study results will be published, but participant identity will not be revealed in any articles or scientific presentations and records will be kept as required by federal and state laws and regulations.

10.1.4 Potential Benefits of the Proposed Research to the Subjects and Others

The main tangible benefits of this study to participants include:

- During Screening, access to the results of their medical examination and laboratory tests. Participants will be advised to contact their personal physician if any unexpected medical condition or problem is identified.
- During the trial, participants will receive testing for the diagnosis of diabetes.
- During the trial, participants will participate in the Support and Education Program, which will provide advice on making important lifestyle changes to delay the onset of diabetes.
- Many participants obtain personal satisfaction from participating in nutritional studies.

Despite these potential direct benefits to study participants, the main benefits of this study will be to others in the future based on the knowledge gained upon completion of the study.

10.1.5 Importance of the Knowledge to be Gained

The knowledge to be gained as a result of the proposed research is important because it may lead to implementation of a successful nutritional intervention for prevention of type 2 diabetes.

10.2. Adverse Events

Adverse events will be collected and documented in accordance with Good Clinical Practice guidelines, local, state and federal regulations.

10.2.1 Definitions and classification of Adverse Event & Serious Adverse Event

Adverse event (AE) is defined as any untoward or unfavorable and unintended medical occurrence (including symptom, physical sign, laboratory finding or disease) observed in or experienced by a participant that is not a benefit to the participant whether or not it is considered study-related by the

research staff.

Adverse Event Classification All AE will be documented in the electronic data capture system characterized by the following criteria: (1) Seriousness (2) Expectedness (3) Relatedness (4) Severity (5) Frequency (6) Outcome (7) Action Taken.

(1) Seriousness is classified as:

- **Serious AE (SAE)** is any event that results in any of the following outcomes:
 - Death.
 - Life-threatening condition (e.g. event that places the participant at immediate risk of death).
 - New inpatient hospitalization or prolongation of existing hospitalization.
 - Persistent or significant disability or incapacity.
 - Congenital anomaly or birth defect.
 - Any other significant hazard that, based upon appropriate medical judgment by the investigators, may jeopardize the participant's health and may require medical or surgical intervention to prevent one of the outcomes listed in this definition.
- **Non-Serious** is any event that does not meet the above criteria for *Serious*

(2) Expectedness is classified as:

- **Expected** event is known to be associated with the intervention or condition under study, in terms of nature, severity or frequency, and has been described as a potential AE in the IRB-approved research protocol, supporting documents and informed consent forms.
- **Unexpected** event has not been previously described as a potential AE in the IRB-approved research protocol, supporting documents or the informed consent forms, in terms of nature, severity or frequency. Unexpected also refers to an adverse event that has not been observed before (i.e. has not been published in medical literature).

(3) Relatedness is classified as:

- **Unrelated.** The adverse event is clearly not related to the study and it is due to extraneous causes (e.g., underlying disease, environment)
- **Unlikely.** The adverse event is doubtfully related to the study. For example, the event:
 1. Does not have temporal relationship to intervention or study procedure.
 2. Could readily have been produced by the participant's clinical state.
 3. Could have been due to environmental or other causes.
 4. Does not follow a known pattern of response to intervention or study procedure.
 5. Does not reappear or worsen with reintroduction of intervention or study procedure.
- **Possible.** The adverse event is possibly related to the study. For example, the event:
 1. Has a reasonable temporal relationship to intervention or study procedure.
 2. Could not readily have been produced by the participant's clinical state.
 3. Could not readily have been due to environmental or other causes.
 4. Follows a known pattern of response to intervention or study procedure.
- **Probable.** The adverse event is likely related to the study. For example, the event:
 1. Has a reasonable temporal relationship to intervention or study procedure.
 2. Could not readily have been produced by the subject's clinical state or have been due to environmental or other causes.
 3. Follows a known pattern of response to intervention or study procedure.
 4. Disappears or decreases with reduction in dose or cessation of intervention or study procedure.

- **Definite.** The adverse event is clearly related to the study. For example, the event:
 1. Has a reasonable temporal relationship to intervention or study procedure.
 2. Could not readily have been produced by the subject's clinical state or have been due to environmental or other causes.
 3. Follows a known pattern of response to intervention or study procedure.
 4. Disappears or decreases with reduction in dose or cessation of intervention or study procedure and recurs with re-exposure.

(4) Severity is classified based on intensity of symptoms, degree of limitation of usual daily activities, or level of abnormality of clinical signs or laboratory parameters, as:

- **Mild.** Awareness of symptoms or signs, but AE is easily tolerated and is of minor irritant type and does not interfere with the participant's usual activity or cause loss of significant time from normal activities. AE may not require therapy or a medical evaluation and is transient and resolves without sequelae.
- **Moderate.** Adverse event introduces a low level of inconvenience or concern to the participant and may interfere with daily activities but participant is able to function with minimal interference. A moderate AE may improve without any therapeutic measure or with simple therapeutic measures.
- **Severe.** Adverse event interrupts the participant's normal daily activities and generally requires systemic drug therapy, major surgery or other treatment; adverse event may be incapacitating.

(5) Frequency is classified as:

- **Single Event**
- **Re-occurring Event**

(6) Outcome. The clinical outcome is classified as:

- **Resolved.** The participant returned to baseline status.
- **Condition still present and under treatment.** Participant has not recovered and symptoms or signs continue.
- **Death.** The SAE form must be completed for this outcome.

(7) Action taken for a specific adverse event in relation to study intervention and procedures is classified as:

- **No action.**
- **Study pills temporarily discontinued,** participant continues in the study.
- **Study pills permanently discontinued,** participant continues in the study.
- **Participation in study permanently discontinued and participant has gone "off study" for safety reasons.** This is expected to be a rare event (e.g. pregnancy) and a formal written "withdrawal of consent" will be requested from the participant.
- **Intervention,** e.g. new medication, surgery, or any other medical procedure.
- **Other treatment:** existing medication dose reduction/interruption or discontinuation.
- **Other (specify).**

10.2.2 Definition of Unanticipated Problem

An unanticipated problem (UAP) is defined as any adverse event, incident, experience, or outcome that meets *all of the following three criteria*:

1. **Unexpected**, in terms of nature, severity, or frequency, given (a) the research procedures that are described in the protocol-related documents, such as the IRB-approved research protocol and informed consent documents; and (b) the characteristics of the study population.
2. **Possibly, probably or definitely related** to participation in the research.
3. Suggests that the research places participants or others at a **greater risk of harm** (including physical, psychological, economic, or social harm) than was previously known or recognized. This criterion (“greater risk of harm”) is always met if the event is a SAE.

In general, an unanticipated problem may require specific action, such as: modification of the research protocol (e.g. changes in inclusion/exclusion criteria; implementation of additional procedures for monitoring participants), suspension of enrollment of new participants, suspension of research procedures in enrolled participants, changes to the informed consent forms or a combination of the above. All three of the criteria in the definition above must be met for an event to be defined as an *Unanticipated Problem*.

10.2.3 Safety Surveillance and Reporting of Adverse Events

The D2d study Safety and Outcomes subcommittee (SOS) has been established to review all SAEs and UAPs as they are reported, review periodic safety reports of all AE and oversee study safety. The subcommittee chair or designee will assess each SAE and UAP, as it occurs, to determine if immediate action is required in response to the event. The subcommittee will meet three times a year (or more frequently as needed) by conference call. During these meetings, the subcommittee discusses all SAE, UAP and summary reports of non-serious AE. The subcommittee also evaluates whether there is any clustering of AE by clinical site. The subcommittee remains masked to patient treatment group during these evaluations. The subcommittee considers whether changes in the protocol (monitoring, consent process, etc.) are indicated based on the occurrence, frequency, or severity of AE, SAE or UAP and provides its recommendations to the Steering Committee and Executive Committee for further discussion and subsequently to the DSMB for approval and implementation. Monitoring of source documents at the sites will include careful attention directed to AE reporting.

Non-serious Adverse Events (AE): All AEs must be reported to the CC by completing the AE-specific eCRF in the EDC system and providing relevant information, within fifteen (15) business days of the site becoming aware of the event. Every month, the study Project Manager and SOS chair (or designee) will review the non-serious AE report and note any events that may be incorrectly classified, identify any trends, and confirm that the AE rates are consistent with pre-study assumptions. Summary reports of AE will be reviewed at each regularly scheduled SOS meeting (three times a year or more frequently if needed). Any recommendation for action will be communicated to the Steering Committee and Executive Committee for further discussion and subsequently to the DSMB for approval and implementation. A summary of all non-serious AE will be provided to the DSMB twice a year.

Sites will also report AE to the site-specific IRB according to local IRB procedures. Reporting should be accompanied by any corrective action plan as developed by the D2d study group.

Serious Adverse Events (SAE): All SAEs must be reported to the CC by completing the AE-specific eCRF in the EDC system and providing relevant information, within five (5) business days of the site becoming aware of the event. Completion of an SAE report through the EDC system will trigger an e-mail notification to the CC and SOS chair (or designee) that will promptly review the SAE. The masked SOS chair (or designee) will assess each SAE to determine whether immediate action is required. If the SOS reviewer determines that additional supporting information is needed to evaluate the SAE, the Project Manager (or designee) will ask the site PI and/or research coordinator to provide the additional information. If the SOS reviewer determines that immediate action should be

considered, s/he will consult with other members of the subcommittee as soon as possible (typically within one week) to recommend a course of action. Any recommendation for action will be communicated to the Steering Committee and Executive Committee for further discussion and subsequently to the DSMB for approval and implementation

Sites will also report SAEs to the site-specific IRB according to local IRB procedures. Reporting should be accompanied by any corrective action plan as developed by the D2d study group.

Unanticipated Problems (UAP): By definition, UAP are events that may require corrective action by the D2d study group; therefore, timely report and evaluation of UAP is of utmost importance. An UAP must be reported to the CC by completing the AE-specific eCRF in the EDC system, and providing relevant information, within two (2) business days of the site becoming aware of the event. Completion of an UAP report through the EDC system will trigger an e-mail notification to the CC and SOS chair (or designee) that will promptly review the UAP. The masked SOS chair (or designee) will assess each UAP to determine whether immediate action is required. If the SOS reviewer determines that additional supporting information is needed to evaluate the UAP, the Project Manager (or designee) will ask the site PI and/or research coordinator to provide the additional information. If the SOS reviewer determines that immediate action should be considered, s/he will consult with other members of the subcommittee as soon as possible (typically within one week) to recommend a course of action. Any recommendation for action will be communicated to the Steering Committee and Executive Committee for further discussion and subsequently to the DSMB for approval and implementation.

Sites will also report UAP to the site-specific IRB according to local IRB procedures. Reporting should be accompanied by any corrective action plan as developed by the D2d study group.

10.3 Data Safety Monitoring Board

A Data and Safety Monitoring Board (DSMB) has been established by the primary sponsoring NIH Institute, NIDDK, to oversee the safety and other aspects of the study. The role of the DSMB is to provide independent oversight and ensure that the study is conducted according to currently established safety and ethical standards. The CC will oversee the provision of data to the DSMB. In general, it is anticipated that the DSMB meets twice a year. The DSMB reviews and evaluates all SAEs, UAPs and outcome measures and also receives a summary report for all non-serious AE. The DSMB charter outlines the method and schedule for AE reporting. Unless specific action is required, the results of the analyses reviewed by the DSMB will not be shared with site investigators. The DSMB will also develop rules for stopping the study. The CC staff will distribute DSMB meeting summary reports to collaborating clinical sites for submission to the sites' IRB.

10.4 Ethical and Regulatory Responsibilities & Statement of Compliance

This study will be carried out in compliance with the IRB-approved protocol and related documents and in accordance with Good Clinical Practice guidelines, the applicable regulatory requirements of the Department of Health and Human Services, the International Conference on Harmonization (ICH) Guidelines and state and local legal and ethical requirements. The following documents contain the policies and procedures designed to ensure adherence to Good Clinical Practices:

1. United States (US) Code of Federal Regulations (CFR) applicable to clinical studies (45 CFR Part 46; 21 CFR Part 50, 21 CFR Part 56, and 21 CFR Part 312)
2. Declaration of Helsinki, concerning medical research in humans (Recommendations Guiding Physicians in Biomedical Research Involving Human Patients, Helsinki 1964, amended Tokyo 1975, Venice 1983, Hong Kong 1989, Somerset West 1996).
3. ICH Harmonized Tripartite Guidelines for Good Clinical Practice 1996

All investigators agree to adhere to the instructions and procedures described in the protocol, thereby adhering to the principles of Good Clinical Practice. All key persons and research staff will have completed educational modules on human subjects protection and are certified by their local IRB. If new information emerges that may affect participants' willingness to continue to participate in the study, the information will be conveyed to participants via a revised informed consent form.

10.5 Confidentiality

All information and data generated as part of the study concerning participants are considered confidential. Access to these files will be restricted to authorized staff of the local investigational team, the CC and Central Laboratory. Authorized regulatory personnel have the right to inspect and copy all records pertinent to this study.

All data will be entered and managed with the use of a 21 CFR Part 11 compliant web-based EDC system, which is platform independent. In compliance with regulations, the EDC features multiple security levels including data element (e.g. restricted access to fields), user (e.g. password authentication access with frequent password changes and lockout after a period of inactivity) and application (e.g. role based access to features, access audit trails).

Each site will maintain a list of participant names with the associated study ID and no other site or entity will have access to this code. All data used in the analysis and reporting of this evaluation will have no identifiable reference to participants.

10.6 Protocol Deviations

A protocol deviation is any departure from the study protocol and Manual of Procedures requirements or Good Clinical Practice guidelines. Protocol deviation may be either on the part of the participant, the investigator, or the study site staff. As a result of deviations, corrective actions are to be developed by the site and implemented promptly.

10.7 Site Monitoring

A representative from the CC (Project Manager and/or assigned Clinical Research Associate) will visit the collaborating clinical sites at periodic intervals, to monitor the collection of data, adherence to the study protocol and regulatory requirements. The case files of a minimum of 10 percent of participants will be reviewed. More frequent monitoring and or additional participant source files may be monitored if warranted based upon requests by the Executive Committee, DSMB, NIDDK or the CC.

During monitoring visits, for each participant selected for review the source documentation verification will be completed for all eCRF data collected up until the date of the visit. Emphasis will be placed on the informed consent process and documentation, study pill storage and accountability and primary outcome assessment.

The study Project Manager (or designee) will source data verify at the Central Laboratory 100% of the following glycemic measures that define the primary outcome.

- FPG
- HbA1c
- 2hPG

10.8 Conflict of Interest

The Executive Committee in conjunction with NIDDK has established a policy for all members of the investigative team to disclose all potential (real or perceived) conflicts of interest.

10.9 ClinicalTrials.gov Requirements

The proposed study is a clinical trial and will be registered in ClinicalTrials.gov.

10.10 Other regulatory requirements and Requirements for Investigational New Drug (IND)

The FDA has determined that an IND is not required for the D2d study.

Participant medical insurance companies will not be billed for any study visits or study procedures. Payment for research-related injury will be determined by each site.

Study records will be maintained for a minimum of 7 years. If the study records will be moved to a different location the site is required to inform the study Principal Investigator at Tufts Medical Center the location of the records.

11. SAMPLE SIZE CALCULATIONS AND DATA ANALYSIS

The primary aim of the D2d study is to assess whether, in participants at risk for diabetes, oral daily vitamin D₃ supplementation will reduce the rate of progression to incident diabetes when compared to placebo.

11.1 Sample Size Calculation (Power Analysis)

The following considerations were used to determine the sample size:

- 1) The primary study outcome is “time to confirmed diabetes”
- 2) Participants will be recruited over a 2-year period (“accrual period”)
- 3) The study duration will be 4 years.
- 4) Participants will be randomized to one of two arms in a 1:1 ratio and followed for a maximum of 4 years for development of the primary outcome.
- 5) The primary hypothesis will be tested at a two-sided type 1 error rate (alpha) of 0.05.
- 6) The incidence rate of confirmed diabetes is assumed to be 10 cases per 100 person-years in the placebo group.
- 7) The loss-to-follow-up rate is assumed to be 5 participants per 100-person years of follow-up.
- 8) If vitamin D therapy is superior to placebo, the hazard ratio will be 0.75 in the vitamin D arm as compared to the placebo group.
- 9) The study will be designed to have power of 90% to detect a hazard ratio of 0.75 or less at the two-sided 0.05 level.
- 10) The study will employ a single interim analysis based on the Peto-Haybittle^{263,264} approach at 70% of expected events.

Based on these assumptions, the required sample size is 2,382 participants (1,191 in each arm). (Power calculations were performed using EAST version 5.4²⁶⁵)

11.1.1 Rationale for the Assumed Conversion Rate of 10% in the Control Arm

The primary outcome of the D2d trial is “time to confirmed diabetes”. The diagnosis of diabetes is based on ADA-based cutoffs for FPG, 2hPG and HbA1c, as defined in section 9. The incidence rate of diabetes can vary considerably based upon a number of factors. In prior type 2 diabetes prevention trials, conducted in a variety of populations worldwide,^{5,6,11-14,17,266-270} the diabetes incidence rates (based only on FPG/2hPG criteria) varied from 2.4% to 23% per year. The most relevant data for the proposed D2d trial come from the DPP (U.S.)⁵ and DREAM (21 countries)¹² studies. The DPP trial recruited participants with FPG 95-125 mg/dL, 2hPG 140-199 mg/dL, and BMI ≥ 24 kg/m². The DPP placebo group had a cumulative incidence of diabetes of ~29% during the 2.8-year mean follow-up (11 cases per 100-person-years). The DREAM trial started recruitment with impaired fasting glucose and impaired glucose tolerance (defined as FPG 110-125 mg/dL and 2hPG <200 mg/dL) or impaired glucose tolerance (defined as FPG ≤ 125 mg/mL and 2hPG 140-199 mg/dL) but later expanded the criteria to include isolated impaired fasting glucose (defined as FPG 110-125 mg/dL and 2hPG <140 mg/dL). The DREAM study had a cumulative incidence of diabetes in the placebo arm of 25% over a 3-year mean follow-up (estimated ~8-9% annually). In two other large type 2 diabetes prevention trials with alpha-glucosidase inhibitors, the cumulative incidence rates in the placebo arm were 42% over 3.3 years (reported 12.1% annually; STOP-IT/Europe)¹¹ and 36% over 2.8 years (estimated ~12-13% annually; Voglibose trial/Japan).¹³ In the CANOE trial (Canada), the cumulative incidence rates in the placebo arm were 42% over 3.9 years (estimated ~10% annually).²⁷⁰ Importantly, in nearly all these studies, the observed annual incidence rate was higher than that assumed in the pre-trial sample size calculations (6.5% [predicted] vs. 11% [actual] in DPP; 4.5% vs. ~8-9% in DREAM; 7% vs. 12 in STOP-IT; 7.7% vs. 12-13% in the Voglibose trial).

We expect the diabetes incidence rate in the D2d study to be at the high end of the rate that would be predicted from the mean annual incidence rate (~9-11%) reported in previous diabetes prevention studies because: (1) the study is targeting a population similar to the DPP (U.S. adults at high risk for type 2 diabetes with similar BMI and age at entry); (2) the definition of ‘at risk for diabetes’ requires 2-out-of-3 glycemic criteria, which will identify participants at higher risk for progression to diabetes; (3) the study will use the current ADA glycemia criteria for diagnosis of diabetes (addition of HbA1c), which will likely raise the incidence rate of diabetes compared with the above studies.

In relation to point (3) above, only one of the published studies on prevention of type 2 diabetes included HbA1c as a criterion for both inclusion and outcome assessment.¹³ The study reported a conversion rate to diabetes in the placebo arm of 36% over 2.8 years. However, this study was conducted in Japan and its definitions of pre-diabetes or diabetes were not consistent with the current ADA criteria; therefore, its relevance to the D2d study is not clear. Adding HbA1c alters the epidemiology of pre-diabetes and diabetes and makes it difficult to predict incidence rates. We reviewed relevant data from recent cross-sectional observational studies that have evaluated the impact of adding HbA1c as a diagnostic criterion. As expected, there is considerable overlap between the HbA1c and FPG/2hPG criteria. Overall, the addition of HbA1c appears to increase prevalence of both pre-diabetes and diabetes.²⁷¹⁻²⁷⁶ For example, Lu et al identified 37% more individuals as having pre-diabetes by HbA1c 5.6-6.5% and identified 9% more individuals as having diabetes by HbA1c >7%.²⁷⁶ Data from NHANES show that an additional ~6% of participants are identified as having diabetes when HbA1c >6.5% criterion is used in addition to FPG/2hrPG.^{272,274} In a recent systematic review that examined ranges of HbA1c and progression to diabetes, the A1c range of 6.0 to 6.5% was associated with a 25 to 50% incidence of diabetes over 5 years.²⁷⁷ In the CaDDM trial,²⁴ among 202 fully screened participants with available data on FPG/2hPG/HbA1c, the addition of HbA1c $\geq 6.5\%$ increased the prevalence of newly diagnosed diabetes from 2% to 7% (unpublished data provided by Dr. Pittas). Finally, in the Pima Indian Longitudinal Study (unpublished data provided by Dr. Knowler), after excluding participants with diabetes at baseline (based on clinical and the 2010 ADA glycemic criteria), there were 392 participants with pre-diabetes (by 2010 ADA criteria) with mean age of 42

years, BMI 39 kg/m² and HbA1c 5.7%. The cumulative incidence of diabetes during a 5-year follow-up period increased from 36% (7.7 cases per 100 person-years), using the old criteria, to 39% (8.6 cases per 100 person-years), using the new expanded criteria, which represents an increase of 12% in the annual incidence rate if HbA1c is added to the FPG/2hPG criteria.

In summary, based on available data in the literature and results of unpublished analyses shown above, it is expected that the addition of HbA1c to the FPG/2hPG diagnostic criteria will increase the number of cases of diabetes diagnosed during follow-up compared to the FPG/2hPG criteria alone. Furthermore, the definition of the main inclusion criterion, pre-diabetes, requiring 2 of 3 criteria (identifying participants at relatively high risk) will increase the incidence rate compared to previous studies. However, the planning committee elected to be conservative in its estimate to ensure adequate power for the primary outcome and has assumed an incidence rate of 10 cases per 100 person-years in sample size calculations.

11.1.2 Rationale for the Assumed Hazard Ratio of 0.75

The planning committee relied on published observational *longitudinal* data and short-term intervention studies to estimate a plausible hazard ratio.

Observational studies: In the Nurses' Health Study, the highest 25OHD concentration (>33 ng/mL) was associated with a reduction in incident diabetes by ~50% over ~10-year follow-up period.¹⁸ In the Framingham Offspring Study, participants in the highest tertile of predicted 25OHD score (>22 ng/mL) had a 40% lower incidence of diabetes during a 7-year follow-up period.²¹ These results are consistent with other recently published observational data.^{26-28,194,195} In a recent meta-analysis that combined data from all available longitudinal observational studies, the pooled relative risk of t2DM comparing the highest with the lowest quartile of 25OHD was 0.59 (0.52, 0.67), with little heterogeneity between the 11 studies included (3,612 cases and 55,713 non-cases) (Figure 11.1).¹⁹⁵

Figure 11.1. Meta-analysis of the association between blood 25OHD concentration and incident type 2 diabetes.¹⁹⁵

In another meta-analysis (unpublished data, manuscript under review), the pooled relative risk for incident type 2 diabetes was 0.62 (95% confidence interval [CI]:0.54-0.70) for the highest vs. lowest 25OHD concentration (Figure 11.2).⁴⁸ A linear trend meta-regression analysis showed that each 4 ng/mL increment in 25OHD level was related to a 4% lower risk of diabetes (RR, 0.96; 95% CI, 0.94-0.98; p for linear trend<0.0001; Figure 11.3).⁴⁸

Based on the observational data, if the proposed D2d intervention (4,000 IU/day of vitamin D) increases participants' mean 25OHD to approximately 40-45 ng/mL from ~20 ng/mL,^{196,199-201} then risk reduction will be approximately 20-25%.

Figure 11.2. Meta-analysis of the association between blood 25OHD concentration and incident type 2 diabetes.⁴⁸

Figure 11.3. Relation between blood 25OHD concentration and risk of incident type 2 diabetes, modeled by quadratic spline regression (unpublished data, manuscript under review).⁴⁸

There are two observational studies of particular importance and relevance to the D2d study that were not included in the above meta-analyses: In the DPP study, among participants with pre-diabetes, there was an inverse linear association between 25OHD and incident diabetes, after multivariate adjustment including change in BMI and physical activity, with the hazard ratio for incident diabetes being lowest (0.46; 95%CI, 0.23 to 0.90) in the highest category (25OHD $\geq$ 50 ng/mL) compared to the lowest category (25OHD $<$ 12 ng/mL) with no evidence of a threshold.²⁵ In another observational study, progression from pre-diabetes to type 2 diabetes was reduced by 73% among those with 25OHD $>$ 28 ng/mL compared to those with 25OHD $<$ 18 ng/mL.¹⁹⁴

Intervention studies: In the CaDDM trial, 2,000 IU/day of vitamin D₃ supplementation, which raised 25OHD to 31 ng/mL, improved measures of beta cell function (disposition index) by ~40% and glycemia (HbA1c) by ~50% after 4 months.²⁴

After taking into consideration all published data and short-term mechanistic studies on vitamin D and diabetes, a hazard ratio of 0.75 (i.e. 25% reduction in risk in the intervention arm) was used as the assumed treatment effect in sample size calculations. A reduction of this magnitude would clearly be clinically significant to public health.

11.2 Data Analysis Plan

Defining the Study Population and Treatment Groups - The primary analysis will be by intention-to-treat, including all randomized participants in their assigned treatment arm and including all events observed during the study irrespective of adherence to assigned treatment. When patients withdraw or are lost to follow-up, follow-up will be censored at the date of the last visit. Exploratory per-protocol analyses and analyses in subgroups defined by level of adherence to study treatment will be undertaken as well, but are not considered part of the confirmatory analysis plan.

Every effort will be made to establish eligibility prior to enrollment and randomization; however, a few enrolled participants may subsequently be found not to meet all enrollment criteria. Most such individuals will be at increased risk for incident diabetes even though some eligibility criteria were not assessed or met. Thus, the primary analyses will include all enrolled participants. If more than 1% of those enrolled do not meet all eligibility criteria, an unlikely scenario, we will perform sensitivity analyses to assess the impact of excluding those individuals.

Baseline Characteristics – Although the randomization procedure should produce balanced treatment groups, relevant demographic (age, gender, race, ethnicity) and baseline clinical characteristics (e.g., BMI, physical activity, family history of diabetes, and 25OHD concentration) of participants will be compared across groups to characterize study participants and to document the success of the randomization procedure. Standard parametric and nonparametric statistical techniques will be used to test for differences in the distributions of baseline characteristics between treatment groups. Statistical significance will be determined from two-sided tests with an alpha level of 0.05. The large size of the trial and the stratification by BMI and race make it likely that differences in the distributions of these potential confounders between treatment groups, if statistically significant, will not be clinically significant.

Primary Outcome – The primary endpoint (outcome variable) is “*time to progression to incident diabetes*”. For most participants, incident diabetes will be diagnosed at one of the regularly scheduled study visits, which will occur every 6 months. In some cases, however, participants will notify study personnel that they have received a diagnosis of diabetes, or been placed on diabetes medication, by their personal physician. In such cases, every effort will be made to assess whether the participant has met the study criteria for incident diabetes. When participants have been placed on a diabetes medication and the diagnosis cannot be confirmed or adjudicated by the safety and outcomes subcommittee, the participant will be considered to have not reached the primary study outcome and

follow-up will be censored at the date of initiation of treatment. Sensitivity analyses will be performed that include these occurrences as instances of incident diabetes.

Statistical Methods - Since the exact time of progression to incident diabetes, defined as the date on which the criteria for incident diabetes would have been met if laboratory tests had been performed, will be unknown for participants who receive a diagnosis of incident diabetes at a regularly scheduled study visit, one could consider statistical methods for interval-censored data for the analysis of the time-to-event variables.²⁷⁸ However, subjects whose diagnosis is initiated by their personal physician will not have a diagnosis date corresponding to a regular visit, and participants will have variable visit schedules. Thus, we have chosen instead to use standard methods for analysis of right-censored time-to-event data, using the incidence date defined in Section 9.1 for the primary outcome. The interval-censored approach and the right-censored time-to-event approach would give similar estimates and standard errors for treatment effects, because the change in approach would have similar effects on the estimated time-to-event distributions in the two treatment groups. Moreover, the notion that each individual participant has a true exact date of onset of diabetes is a somewhat artificial concept, in that an individual will not consistently meet the diagnostic criteria on successive days as they transition from pre-diabetes to incident diabetes.

Kaplan-Meier estimates of “time to confirmed diabetes” distributions will be calculated for each treatment group. The log-rank test will then be used to perform an adjusted comparison of the time-to-event distributions in the two treatment groups. For the primary outcome analysis, participants will be considered “administratively censored” if they remain in the trial without meeting the criteria for incident diabetes until the conclusion of the study. Follow-up of participants who withdraw or are lost to follow up will be “censored” on the date of their last follow-up visit. All p values examined for statistical significance will be two tailed, and p-values below 0.05 will be considered statistically significant. Cox proportional hazard models²⁷⁹ will be used to calculate an estimate of the adjusted hazard ratio. To construct the model for the adjusted analysis, we will first construct a regression model that does not include the indicator for treatment group. Age, race, ethnicity, BMI, and other variables (fasting glucose, 2-hr glucose, HbA1c and 25OHD) to be specified a priori will be forced into the model. Variables will then be added in a step-up fashion from a list of candidates selected a priori. Covariates making a statistically significant contribution to the proportional hazards regression model will be included in the multivariate model. When the step-up procedure has been completed, the covariate for treatment group will be added to the model. The regression coefficient for treatment group in this multiple regression model will be the adjusted estimate of the log hazard ratio.

Subgroup Analyses - Pre-specified subgroup analyses will be performed in participant subgroups defined by baseline variables, e.g., race (self-reported definitions of White, vs. non-White e.g. Black/African American, American Indian, Alaska Native); ethnicity (Hispanic vs. Non-Hispanic); BMI (two groups based on median value); waist circumference (two groups based on median value);¹⁸⁶ age (two groups based on median value); geographic location (two groups, above or below 42° latitude) and 25OHD concentration. Each analysis of participant subgroups will include a test for interaction. Effect modification will be claimed only if the test for interaction reaches statistical significance. These analyses, although pre-specified, are considered exploratory as the study is not powered for such analyses and multiple comparisons must be considered when interpreting findings that are nominally statistically significant. We will also perform “per-protocol” and “on-treatment” analyses, where treatment is defined by pill count or achieved 25OHD concentration. These analyses will also be considered to be exploratory.

Missing Data - Missing data are inevitable in clinical research. Every effort will be made to minimize missing data in the D2d study. The primary methods of data analysis assume that censoring for time-to-event variables is non-informative. However, as recommended in the recent report of the Institute of Medicine, we will perform sensitivity analyses to assess the degree to which the results are

sensitive to the validity of the assumptions of non-informative censoring or non-informative missingness.

Data Monitoring Plan – Methods for interim analysis of accumulating data will be reviewed and approved by the Data and Safety Monitoring Board (DSMB). The DSMB will regularly review accumulating safety and efficacy data to assure that continuation of the study remains scientifically and ethically appropriate. As a specific part of this monitoring activity, we recommend that a single formal interim analysis of the accumulating primary endpoint data take place when 70% of the expected events have accrued. The stopping boundary for the interim analysis will be based on the Peto-Haybittle approach.^{263,264} With this stopping boundary, the nominal P value representing statistical significance will be 0.0001, corresponding to a Z score of 3.89.

The D2d coordinating center will prepare the reports on behalf of the DSMB, whose members will review the data and advise the sponsor (NIDDK) whether (1) there is evidence that the intervention is clearly better or worse than placebo in relation to the primary outcome, and (2) the DSMB recommends a change in the study plan based on safety considerations.

Seasonal and Geographic Variability – Given that the cohort will be recruited at a constant rate throughout the calendar year and outcomes will be determined every 6 months, the potential for seasonal variability confounding the association between vitamin D supplementation and outcomes is low. We will test this assumption in the analyses, and if needed, we will adjust for the month of the year at entry into the study. All analyses will adjust for site, as routinely done in multicenter studies, which will also approximate latitude at each of the participating sites. Given the age group, we anticipate few participants moving residence during the study.

12. FUNDING, STUDY ORGANIZATION, ADMINISTRATION AND GOVERNANCE

12.1 Sponsors

The planning phase of the D2d study was funded by the National Institute of Diabetes and Digestive and Kidney Diseases (NIDDK) of the National Institutes of Health (NIH) through the Multi-Center Clinical Study Implementation Planning Grant (U34) to Tufts Medical Center in Boston, Massachusetts. The active phase of the study is supported primarily by NIDDK and the Office of Dietary Supplements through the U01 Multi-Center Clinical Study Cooperative Agreement (U01) to Tufts Medical Center, which will establish sub-award agreements with each collaborating clinical site and core units (e.g. Central Laboratory, drug distribution center) to reimburse each site and core unit for their activities related to the D2d study. The funding agency (NIDDK) and the study investigators work as partners; however, the primary responsibility for the D2d study planning and conduct is with the study's Principal Investigator and the CC. Representatives from NIDDK participate in all phases of planning, development of the protocol, development of policies and procedures, implementation and monitoring of study performance and safety, data analyses and interpretation and dissemination of study findings. The sponsor has no role in the decision to submit the report for publication.

12.2 Organizational Overview

Overall study leadership is provided by the Steering Committee while the Executive Committee acts as the operational arm of the Steering Committee. The D2d Coordinating Center (CC) is established in the Division of Endocrinology at Tufts Medical Center. The CC provides overall study organization and administration, and manages day-to-day operations by working directly with the collaborating sites, other study core units and study committees and subcommittees. The CC implements the study protocol; oversees the development of the Manual of Procedures; monitors participant recruitment and treatment delivery; evaluates data collection and management; oversees quality assurance procedures; monitors participant safety; and implements changes and enhancements to the study as recommended by the Steering Committee. The CC also develops the data collection processes, performs data monitoring, data cleaning and analyses and contributes to manuscript writing. The *Drug Distribution Center*, located at the VA Cooperative Studies Program, Clinical Research Pharmacy Coordinating Center, conducts the randomization and distribution of study drug to the sites. The *Central Laboratory*, located at the University of Vermont in Burlington, Vermont, coordinates collection of study specimens from collaborating sites, conducts laboratory measurements and serves as a central repository for short and intermediate-term storage of human blood and urine samples. Certain laboratory assays (e.g. 25OHD, DNA extraction from stored whole blood) will be done at Tufts Medical Center. After the study is completed, long-term storage of human blood and urine samples will be transitioned to the NIDDK Repository.

12.3 Study Leadership and Governance

12.3.1 Executive Committee (EC)

The EC acts as the operational arm of the Steering Committee (SC) and makes scientific, administrative and fiscal decisions, on behalf of the SC, for day-to-day operational issues requiring prompt action. The committee develops timelines for the accomplishment of tasks, appoints (and disbands) subcommittees as the need arises and selects subcommittee members and chairs, presents information to the sponsor, and develops Steering Committee meeting agendas.

12.3.2 Steering Committee (SC)

The SC provides scientific leadership for the study. The committee works closely with its operational arm, the EC, and the SC subcommittees. The committee reports to the primary study sponsor (NIDDK), via the EC. The committee is comprised of all standing members of the EC plus the Principal Investigator from each collaborating site and the Central Laboratory

12.3.2.1 Steering Committee Subcommittees

There are 7 standing subcommittees, which are established to monitor specific components of the stud conduct and to provide periodic status reports to the Steering and Executive Committees.

The following subcommittees have been established:

Conflict of Interest Subcommittee (CIS): The subcommittee reviews all conflict of interest forms in which there has been a disclosure. The committee will determine if a potential conflict of interest exists, and will develop and implement a management plan that will specify the actions that have been and/or will be taken to eliminate or limit the potential impact of such conflict(s) on the study's credibility. The subcommittee works closely with the sponsor to evaluate and mitigate conflicts of interest

Recruitment and Retention Subcommittee (RRS): The subcommittee reviews and approves the collaborating sites' recruitment plans prior to the start of the study and monitors recruitment progress and retention and adherence to study procedures. Rates of participant retention and prompt and complete data capture will serve as quality measures of performance by the sites. Pre-specified site-specific targets for optimal performance are defined and should be met to achieve high quality of trial conduct. The subcommittee reviews these measures regularly and makes recommendations (general or site-specific) to improve these rates and ensure that sites meet their target recruitment/retention goals. The subcommittee makes recommendations to the Executive Committee regarding the need for additional sites, if recruitment is slower than anticipated.

Support and Education Subcommittee (SES): The subcommittee develops the Support and Education Program that will be implemented during the study. The subcommittee reviews and approves the education materials on the current lifestyle recommendations for prevention of type 2 diabetes that will be provided to all participants at baseline. The subcommittee also develops program themes and content for use during the SEP group meetings that will be held at each site twice a year. The goals of the SEP meetings will be: (1) to provide participants with up-to-date information on the lifestyle recommendations for the prevention of type 2 diabetes and (2) to promote participant retention. Towards these goals, the SES works closely with the RRS.

Research Coordinators Subcommittee (RCS): The subcommittee is comprised of the research coordinators from each site and representatives from the CC. The major objective of the subcommittee is to assure communication among the sites with respect to overall study coordination and share best ideas and problem solve. The coordinators are closest to the day-to-day issues at the sites; therefore, they are expected to be an invaluable resource to the study and are encouraged to make recommendations regarding the study conduct to the Steering and Executive Committees for review and consideration. The Chairperson of the RCS is a member of the EC.

Safety & Outcomes Subcommittee (SOS): The subcommittee implements the Data Safety Monitoring Plan. The subcommittee reviews all serious adverse events (SAE) and unanticipated problems (UAP) as they are reported, reviews periodic safety reports of all adverse events (AE) and oversees study safety. The subcommittee chair or designee assesses each SAE and UAP to determine if immediate action is required in response to the event. The subcommittee meets three times a year (or more frequently if needed) by conference call. During these meetings, the subcommittee discusses SAE, UAP and summary reports of non-serious AE. The subcommittee also

evaluates whether there is any clustering of AEs, SAEs or UAPs by clinical site. The subcommittee remains masked to patient treatment group during these evaluations. The subcommittee considers whether changes in the protocol (monitoring, consent process, etc.) are indicated based on the occurrence, frequency, or severity of AE, SAE or UAP and provides its recommendations to the Steering and Executive Committees for further discussion and subsequently to the DSMB for approval and implementation. The subcommittee also provides adjudication for secondary outcomes.

Ancillary Study Subcommittee (ASS): The subcommittee is responsible for establishing and overseeing the Ancillary Studies Policies and Procedures and ensuring that the policy is followed. The subcommittee is responsible for evaluating ancillary study applications and making recommendations to the Steering Committee regarding the proposals and monitors progress of approved ancillary studies.

Publications & Presentations Subcommittee (PPS): The subcommittee develops and oversees the policies and procedures by which D2d investigators will interpret data analyses and will coordinate publications and presentations of study results. The subcommittee is responsible for establishing and overseeing the Publications and Presentations Policy and ensuring that the policy is followed. The subcommittee reviews and approves all publications and presentations related to the D2d study, including those from ancillary studies, prior to submission. The subcommittee monitors the progress of all proposed manuscripts to ensure prompt completion and publication.

12.3.3 Clinical Outcomes Committee (COC)

The committee, which is independent of the D2d Study Group, is formed to review and adjudicate the diagnosis of diabetes that is made outside of the D2d study or initiation of diabetes-specific medication (for any reason) when study-specific glycemic data are not available. The COC is composed of clinical diabetes experts who have no real or perceived conflict of interest related to the D2d study, D2d Study Group, sponsor or study core units.

12.4 Role of Industry

Industry may contribute resources to the study and will be acknowledged appropriately; however, industry will play no role in the design and conduct of the study, data analysis, interpretation or publication of study results.
